#### Abstract

One main limitation of the existing optimal scaling results for Metropolis-Hastings algorithms is that the assumptions on the target distribution are unrealistic. In this paper, we consider optimal scaling of random-walk Metropolis algorithms on general target distributions in high dimensions arising from practical MCMC models from Bayesian statistics. For optimal scaling by maximizing expected squared jumping distance (ESJD), we show the asymptotically optimal acceptance rate 0.234 can be obtained under general realistic sufficient conditions on the target distribution. The new sufficient conditions are easy to be verified and may hold for some general classes of MCMC models arising from Bayesian statistics applications, which substantially generalize the product i.i.d. condition required in most existing literature of optimal scaling. Furthermore, we show one-dimensional diffusion limits can be obtained under slightly stronger conditions, which still allow dependent coordinates of the target distribution. We also connect the new diffusion limit results to complexity bounds of Metropolis algorithms in high dimensions.

## 1. Introduction

Markov chain Monte Carlo (MCMC) algorithms [15,28,38,45,53] are now routinely used in many fields to obtain approximations of integrals that could not be tackled by common numerical methods, because of the simplicity and the scalability to high-dimensional settings. The running times of MCMC algorithms are an extremely important issue of practice. They

[^0]have been studied from a variety of perspectives, including convergence "diagnostics" via the Markov chain output [27], proving weak convergence limits of sped-up versions of the algorithms to diffusion limits [54,55], directly bounding the convergence in total variation distance $[3,26,31,32,44,60-63]$, and non-asymptotic guarantees when the target distribution has a smooth and log-concave density, e.g. [12,21,22,24] and the references therein.

The optimal scaling framework [54-56] is one of the most successful and practically useful ways of performing asymptotic analysis of MCMC methods in high-dimensions. Optimal scaling results (e.g. [5,8,17,34,35,46-49,57,76]) facilitate optimization of MCMC performance by providing clear and mathematically-based guidance on how to tune the parameters defining the proposal distribution for Metropolis-Hastings algorithms [30,43]. For instance, classical results include tuning the acceptance probabilities to 0.234 for random-walk Metropolis algorithm (RWM) [54] and 0.574 for Metropolis-adjusted Langevin algorithm (MALA) [55]. Moreover, optimal scaling results have been used to analyze and compare a wide variety of MCMC algorithms, such as Hamiltonian Monte Carlo (HMC) [9], Pseudo-Marginal MCMC [68], multiple-try MCMC [7]. This yields guidance which is widely used by practitioners, especially via self-tuning or Adaptive MCMC methodologies [1,64].

In the original paper, Roberts and Rosenthal [54] dealt with the RWM algorithm starting in stationarity for target distributions which have i.i.d. product forms. The i.i.d. condition for the target and the assumption for the chain to start in stationarity are two main limitations of the optimal scaling framework. Particularly, the product i.i.d. condition is very restrictive. From a practitioner's perspective, target distributions of the i.i.d. forms are too limited a class of probability distributions to be useful, since they can be tackled by sampling a single one-dimensional target due to the product structure. To this day, optimal scaling results have mainly been proved for target distributions with a product structure, which severely limits their applicability. On the other hand, practitioners use these tuning criteria far outside the class of target distributions of product i.i.d. forms. For example, extensive simulations [56,66] show that these optimality results also hold for more complex target distributions.

There exists only a few extensions for correlated targets and most of them are derived for very specific models. For example, Breyer and Roberts [14] studied target densities which are Gibbs measures and Roberts and Rosenthal [56] studied inhomogeneous target densities. Breyer et al. [13] studied target distributions arising in nonlinear regression and have a mean field structure. Neal and Roberts [46] considered the case where updates of highdimensional Metropolis algorithms are lower dimensional than the target density itself. Later, Bédard and Rosenthal [8] studied independent targets with different scales (see also [4,5]) and Bédard [6] studied a special family of hierarchical target distributions. Neal and Roberts [47] studied spherically constrained target distributions and non-Gaussian proposals [48]. Sherlock and Roberts [67] considered elliptically symmetric unimodal targets. Neal et al. [49] studied densities with bounded support. Durmus et al. [23] considered target distributions which are differentiable in $L^{p}$ mean. Recently, Mattingly et al. [41] studied diffusion limits for a class of high-dimensional measures found from the approximation of measures on a Hilbert space which are absolutely continuous with respect to a Gaussian reference measure (see also [10,11,20,51]). Important examples of this scenario required by Mattingly et al. [41] in uncertainty quantification problems are given in [16,29,70]. However, in this paper we shall concentrate on the situation where absolute continuity with respect to a Gaussian is not a reasonable assumption, as is the case in many Bayesian statistics applications.

Furthermore, we do not consider the transient phase of the Metropolis-Hasting algorithms in this paper. The transient phase of high-dimensional Metropolis-Hasting algorithms is studied
for example in [17,34-37]. Kuntz et al. [37] studied the RWM algorithm starting out of stationarity in the settings of Mattingly et al. [41] and Jourdain et al. [35] when non-product target distributions are defined in a Hilbert space being absolute continuous with respect to some Gaussian measures. Such target distributions in [37] can arise for example in Bayesian nonparametric settings, but not in many other Bayesian statistics applications which we focus on in this paper.

In this paper, we consider optimal scaling of RWM algorithms on general target distributions in high dimensions arising from practical MCMC models in Bayesian statistics. First, for optimal scaling by maximizing expected squared jumping distance (ESJD), we show the asymptotically optimal acceptance rate 0.234 can be obtained under general sufficient conditions on the target distribution. Very briefly speaking, 0.234 is asymptotically optimal if (i) each coordinate of the Markov chain is only strongly dependent with a subset of other coordinates (see assumptions (A1) and (A3)); (ii) the target distribution satisfies some smoothness conditions (see assumptions (A2) and (A4)); (iii) as the dimension goes to infinity, a key quantity of "roughness" of the target concentrates to a nonzero value (see assumption (A5)). The new sufficient conditions are easy to check in practice and may hold for some general classes of practical MCMC models. Our results substantially generalize the commonly used product i.i.d. condition. Furthermore, we show one-dimensional diffusion limits can also be obtained under relaxed conditions which still allow dependent coordinates of the target distribution. Finally, we also connect the new results of diffusion limits to complexity bounds of RMW algorithms in high dimensions. Note that although the whole paper is focused on RWM algorithm, we believe the technical proofs in this paper can be used to relax restrictive conditions on the target distribution for more general Metropolis algorithms.

The paper is organized as follows. In Section 2, we give a brief background review of optimal scaling for Metropolis-Hastings algorithms and complexity bounds via diffusion limits. In Section 3, we present our main results, which include three parts: optimal scaling by maximizing ESJD, optimal scaling via diffusion limits, and complexity bounds via diffusion limits. In Section 4, we demonstrate the new optimal scaling result holds for some useful MCMC models. In Appendix A, we prove Theorem 3.10, which is one of our main results. The proofs of lemmas used for proving Theorem 3.10 and other main results, such as Theorems 3.19 and 3.21, are delayed to Appendices B-D.

## 2. Background on optimal scaling

Practical implementations of Metropolis-Hastings algorithms suffer from slow mixing for at least two reasons: the Markov chain moves very slowly to the target distribution when the proposed jumps are too short; the Markov chain stays at a state for most of the time when the proposed jumps are long but the chain ends up in low probability areas of the target distribution. The optimal scaling problem [54] considers the choice of proposed distribution to optimize mixing of the Metropolis-Hastings algorithm. We focus on one of the most popular MCMC algorithms, the RWM algorithm. This algorithm proceeds by running a Markov chain $\left\{X^{d}(t), t=0, \ldots, \infty\right\}$ as follows. Given a target distribution $\pi^{d}$ on the state space $\mathbb{R}^{d}$ and the current state $X^{d}(t)=x^{d}$, a new state is proposed by $Y^{d} \sim \mathcal{N}\left(x^{d}, \sigma_{d}^{2} I\right)$, which is sampled from a multivariate Gaussian distribution centered at $x^{d}$, then the proposal is accepted with probability $\min \left\{1, \pi^{d}\left(Y^{d}\right) / \pi^{d}\left(x^{d}\right)\right\}$ so that $X^{d}(t+1)=Y^{d}$. Otherwise the proposal is rejected and $X^{d}(t+1)=x^{d}$. This is precisely to ensure the Markov chain is reversible with respect to the target distribution $\pi^{d}$. It can be shown that the normal proposals automatically make the RWM
algorithm $\pi^{d}$-irreducible, aperiodic, and hence ergodic [42,59]. Therefore, it will converge asymptotically to $\pi^{d}$ in law. Note that the only computational cost involved in calculating the acceptance probabilities is the relative ratio of densities. Within the class of all MetropolisHastings algorithms, the RWM algorithm is still widely used in many applications because of its simplicity and robustness.

### 2.1. Optimal scaling via diffusion limits

The most common technique to prove optimal scaling results is to show a weak convergence to diffusion limits as the dimension of a sequence of target densities converges to infinity $[54,55]$. More specifically, even though different coordinates of the Markov chain are not independent nor even individually Markovian, when the proposal is appropriately scaled according to the dimension, the sequence of sped-up stochastic processes formed by one fixed coordinate of each Markov chain converges to an appropriate Markovian Langevin diffusion process. The limiting diffusion limit admits a straightforward efficiency maximization problem which leads to asymptotically optimal acceptance rate of the proposed moves for the Metropolis-Hastings algorithm. In [54], the target distribution $\pi^{d}$ is assumed to be an $d$-dimensional product density with respect to Lebesgue measure, that is

$$
\begin{equation*}
\pi^{d}\left(x^{d}\right)=\prod_{i=1}^{d} f\left(x_{i}\right), \tag{1}
\end{equation*}
$$

where $x^{d}=\left(x_{1}, x_{2}, \ldots, x_{d}\right)$. It is shown that with the choice of scaling $\sigma_{d}^{2}=\ell^{2} /(d-1)$ for some fixed $\ell>0$, individual components of the resulting Markov chain converge to the solution of a stochastic differential equation (SDE). More specifically, denoting $X^{d}=$ ( $X_{1}^{d}, X_{2}^{d}, \ldots, X_{d}^{d}$ ), the first coordinate of the RWM algorithm, $X_{1}^{d}$, sped up by a factor of $d$, i.e. $\left\{X_{1}^{d}(\lfloor d t\rfloor), t=0,1, \ldots\right\}$, converges weakly in the usual Skorokhod topology to a limiting ergodic Langevin diffusion.

Proposition 2.1 ([54, Theorem 1.1]). Suppose density $f$ satisfies that $f^{\prime} / f$ is Lipschitz continuous and

$$
\begin{equation*}
\int\left[\frac{f^{\prime}(x)}{f(x)}\right]^{8} f(x) \mathrm{d} x<\infty, \quad \int\left[\frac{f^{\prime \prime}(x)}{f(x)}\right]^{4} f(x) \mathrm{d} x<\infty \tag{2}
\end{equation*}
$$

Then for $U^{d}(t):=X_{1}^{d}(\lfloor d t\rfloor)$, as $d \rightarrow \infty$, we have $U^{d} \Rightarrow U$, where $\Rightarrow$ denotes weak convergence in Skorokhod topology, and $U$ satisfies the following Langevin SDE

$$
\begin{equation*}
\mathrm{d} U(t)=(h(\ell))^{1 / 2} \mathrm{~d} B(t)+h(\ell) \frac{f^{\prime}(U(t))}{2 f(U(t))} \mathrm{d} t \tag{3}
\end{equation*}
$$

with $h(\ell):=2 \ell^{2} \Phi(-\ell \sqrt{\tilde{I}} / 2)$ is the speed measure for the diffusion process, $\tilde{I}:=\int\left[\frac{f^{\prime}(x)}{f(x)}\right]^{2}$ $f(x) \mathrm{d} x$, and $\Phi$ being the standard Gaussian cumulative density function.

This weak convergence result leads to the interpretation that, started in stationarity and applied to target measures of the i.i.d. form, the RWM algorithm will take on the order of $d$ steps to explore the invariant measure. Furthermore, it may be shown that the value of $\ell$ which maximizes the speed measure $h(\ell)$ and, therefore, maximizes the speed of convergence of the limiting diffusion, leads to a universal acceptance probability, for the RWM algorithm applied to targets of i.i.d. forms, of approximately 0.234 . Proposition 2.1 is proved in [54]
using the generator approach [25]. The same method of proof has also been applied to derive optimal scaling results for other types of MCMC algorithms: for example, the convergence of MALA to diffusion limits when $\sigma_{d}^{2}=\ell^{2} / d^{1 / 3}$ (see e.g. [13,17,46,55,56]) with asymptotically optimal acceptance rate 0.574 .

### 2.2. Optimal scaling by maximizing ESJD

Another popular technique to prove optimal scaling is by maximizing expected squared jumping distance (ESJD) [2,50,57], which is defined as follows.

## Definition 2.2 (Expected Squared Jumping Distance).

$$
\begin{equation*}
\operatorname{ESJD}(d):=\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y^{d}}\left[\left\|Y^{d}-X^{d}\right\|^{2}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)\right] \tag{4}
\end{equation*}
$$

where the expectation over $Y^{d}$ is taken for $Y^{d} \sim \mathcal{N}\left(x^{d}, \frac{\ell^{2}}{d-1} I\right)$ for given $X^{d}=x^{d}$, and $\|\cdot\|$ denotes the Euclidean distance, i.e. $\left\|Y^{d}-X^{d}\right\|^{2}=\sum_{i=1}^{d}\left(Y_{i}-X_{i}\right)^{2}$.

Choosing a proposal variance to maximize ESJD is equivalent to minimizing the firstorder auto-correlation of the Markov chain, and thus maximizing the efficiency if the higher order auto-correlations are monotonically increasing with respect to the first-order autocorrelation [50]. Furthermore, if weak convergence to a diffusion limit is established, then the ESJD converges to the quadratic variance of the diffusion limit. This suggests that maximizing the ESJD is a reasonable problem. For example, Atchadé et al. [2] considered to maximize the ESJD to choose optimal temperature spacings for Metropolis-coupled Markov chain Monte Carlo and simulated tempering algorithms. Later, Roberts and Rosenthal [57] proved a diffusion limit for the simulated tempering algorithms. Using a new comparison of asymptotic variance of diffusions, Roberts and Rosenthal [57] showed the results in the choice of temperatures in [2] do indeed minimize the asymptotic variance of all functionals. Another example is the optimal scaling result for HMC, with asymptotically optimal acceptance rate 0.651 when $\sigma_{d}^{2}=\ell^{2} / d^{1 / 4}[9]$, is proven by maximizing the ESJD.

Although establishing weak convergence of diffusion limits gives stronger guarantee than maximizing ESJD, the price to pay is to require stronger conditions on the target distribution. Maximizing ESJD instead can lead to (much) weaker conditions on the target distribution. Later in this paper, we will show that we are able to relax the restrictive product i.i.d. condition on the target distribution for both cases. In particular, the new sufficient conditions on the target distribution for maximizing ESJD are weak enough to allow target distributions arising from realistic MCMC models.

### 2.3. Background on complexity bounds

Because of the big data world, in recent years, there is much interest in the "large $d$, large $n$ " or "large $d$, small $n$ " high-dimensional regime, where $d$ is the number of parameters and $n$ is the sample size. Rajaratnam and Sparks [52] use the term convergence complexity to denote the ability of a high-dimensional MCMC scheme to draw samples from the posterior, and how the ability to do so changes as the dimension of the parameter set grows. This requires the study of computer-science-style complexity bounds [18,19] in terms of running time complexity order as the "size" of the problem goes to infinity. In the Markov chain context, computer
scientists have been bounding convergence times of Markov chain algorithms focusing largely on spectral gap bounds for Markov chains [39,40,69,72-74]. In contrast, statisticians usually study total variation distance or other metric for MCMC algorithms. In order to bridge the gap between statistics-style convergence bounds, and computer-science-style complexity results, in one direction, Yang and Rosenthal [75] recently shows that complexity bounds for MCMC can be obtained by quantitative bounds using a modified drift-and-minorization approach. In another direction, Roberts and Rosenthal [58] connect existing results on diffusion limits of MCMC algorithm to the computer science notion of algorithm complexity. The main result in [58] states that any weak limit of a Markov process implies a corresponding complexity bound in an appropriate metric. More specifically, Roberts and Rosenthal [58] connect the diffusion limits to complexity bound using the Wasserstein metric. Let $(\mathcal{X}, \mathcal{F}, \rho)$ be a general measurable metric space, the distance of a stochastic process $\{X(t)\}$ on $(\mathcal{X}, \mathcal{F})$ to its stationary distribution $\pi$ is defined by the KR distance

$$
\begin{equation*}
\left\|\mathcal{L}_{x}(X(t))-\pi\right\|_{\text {KR }}:=\sup _{g \in \operatorname{Lip}_{1}^{1}}|\mathbb{E}[g(X(t))]-\pi(g)| \tag{5}
\end{equation*}
$$

where $\mathcal{L}_{x}(X(t))$ denotes the law of $X(t)$ conditional on starting at $X(0)=x, \pi(g):=$ $\int g(x) \pi(\mathrm{d} x)$ is the expected value of $g$ with respect to $\pi$, 'KR' stands for 'KantorovichRubinstein', and $\operatorname{Lip}_{1}^{1}$ is the set of all functions $g$ from $\mathcal{X}$ to $\mathbb{R}$ with Lipschitz constant no larger than 1 and with $|g(x)| \leq 1$ for all $x \in \mathcal{X}$, i.e.

$$
\begin{equation*}
\operatorname{Lip}_{1}^{1}:=\{g: \mathcal{X} \rightarrow \mathbb{R},|g(x)-g(y)| \leq \rho(x, y), \forall x, y \in \mathcal{X},|g| \leq 1\} . \tag{6}
\end{equation*}
$$

Note that the KR distance defined in Eq. (5) is exactly the 1st Wasserstein metric. Then it can be shown that the $\pi$-average of the KR distance to stationarity from all initial states $X(0)$ in $\mathcal{X}$ is non-increasing, which leads to the following complexity linking proposition.

Proposition 2.3 ([58, Theorem 1]). Let $X^{d}=\left\{X^{d}(t), t \geq 0\right\}$ be a stochastic process on $(\mathcal{X}, \mathcal{F}, \rho)$, for each $d \in \mathbb{N}$. Suppose $X^{d}$ converges weakly in the Skorokhod topology as $d \rightarrow \infty$ to a càdlàg process $X^{\infty}$. Assume these processes all have the same stationary distribution $\pi$ and that $X^{\infty}$ converges weakly to $\pi$. Then for any $\epsilon>0$, there are $D<\infty$ and $T<\infty$ such that

$$
\begin{equation*}
\mathbb{E}_{X^{d}(0) \sim \pi}\left\|\mathcal{L}_{X^{d}(0)}\left(X^{d}(t)\right)-\pi\right\|_{K R}<\epsilon, \quad \forall t \geq T, d \geq D . \tag{7}
\end{equation*}
$$

Proposition 2.3 allows us to bound the convergence of the sequence of processes uniformly over all sufficiently large $d$, if the sequence of Markov processes converges weakly to a limiting ergodic process. Combining Proposition 2.3 with previously-known MCMC diffusion limit results, Roberts and Rosenthal [58] prove that the RWM algorithm in $d$ dimensions takes $\mathcal{O}(d)$ iterations to converge to stationarity. However, in [58], the target distribution needs to be product i.i.d. with density satisfies all the assumptions of Proposition 2.1. Furthermore, the condition Eq. (2) is replaced by a stronger condition

$$
\begin{equation*}
\int\left[\frac{f^{\prime}(x)}{f(x)}\right]^{12} f(x) \mathrm{d} x<\infty, \quad \int\left[\frac{f^{\prime \prime}(x)}{f(x)}\right]^{6} f(x) \mathrm{d} x<\infty \tag{8}
\end{equation*}
$$

## 3. Main results

In this section, we show our main results on optimal scaling of RWM algorithms on general target distributions. We first consider optimal scaling by maximizing ESJD in Section 3.1. We
show asymptotic form of the ESJD in Theorem 3.10 under very mild conditions on the target distribution. Then we show in Theorem 3.13 that if we directly maximize the asymptotic ESJD, we can obtain 0.234 as an upper bound of the asymptotically optimal acceptance rate. Next, we show the acceptance rate 0.234 is asymptotically optimal under one more weak law of large number (WLLN) condition on the target distribution in Theorem 3.14. In order to give the reader a brief idea that to what extend the class of target distributions can be enlarged. We first present an example of a non-product non-i.i.d. class of distributions, which is a straightforward corollary of our main result in Theorem 3.14. Note that our main result includes much more general class of distributions than this simple example. Recall that a (probabilistic) graphical model is a family of probability distributions defined in terms of a directed or undirected graph [33]. Suppose that the statistical model can be represented as a graphical model, then we have the following corollary.

Corollary 3.1 (A Simple Corollary of Theorem 3.14). If the following three conditions hold, 0.234 is indeed the asymptotic acceptance rate: (i) in the graph representation, each node of the graph has at most o( $d^{1 / 4}$ ) links; (ii) the target density $\pi^{d}$ is bounded and $\log \pi^{d}$ has up to the third bounded partial derivatives; (iii) for $X^{d} \sim \pi^{d}, \frac{1}{d} \sum_{i=1}^{d}\left(\frac{\partial}{\partial x_{i}} \log \pi^{d}\left(X^{d}\right)\right)^{2}$ converges to a positive constant as $d \rightarrow \infty$.

In Section 3.2, we consider optimal scaling via diffusion limits. We prove the new conditions for weak convergence to diffusion limits in Theorem 3.19. We then strengthen this result to consider fixed starting state in Theorem 3.21. Finally, in Section 3.3, we apply our new result on diffusion limits with fixed starting state to obtain complexity bounds for the RMW algorithm, which is given in Corollary 3.23.

Before presenting our main results, we first define a sequence of "sets of typical states".
Definition 3.2. We call $\left\{F_{d}\right\}$ a sequence of "sets of typical states" if $\pi^{d}\left(F_{d}\right) \rightarrow 1$.
Next, we enlarge $\left\{F_{d}\right\}$ in different ways, which will be used later for the new conditions on the target.

Definition 3.3. For a given sequence of "sets of typical states" $\left\{F_{d}\right\}$, we define

$$
\begin{equation*}
F_{d}^{(i)}:=\left\{\left(x_{1}, \ldots, x_{i-1}, y, x_{i+1}, \ldots, x_{d}\right): \exists\left(x_{1}, \ldots, x_{d}\right) \in F_{d}, \text { such that }\left|y-x_{i}\right|<\sqrt{\log d / d}\right\} . \tag{9}
\end{equation*}
$$

Furthermore, we define $F_{d}^{+}:=\bigcup_{i=1}^{d} F_{d}^{(i)}$.
Remark 3.4. It is clear from the definitions that $F_{d}^{(i)}$ is to enlarge the $i$ th coordinate of $x^{d} \in F_{d}$ by covering it with an open interval $\left(x_{i}-\sqrt{\log d / d}, x_{i}+\sqrt{\log d / d}\right) ; F_{d}^{+}$is the union of $F_{d}^{(i)}, i=1, \ldots, d$. Then clearly we have $F_{d} \subseteq F_{d}^{(i)} \subseteq F_{d}^{+}$. In practice, the difference between $F_{d}^{+}$and $F_{d}$ is usually asymptotically ignorable in high dimensions. $\triangleleft$

Finally, we introduce the idea of "neighborhoods" of a coordinate, which is later used to capture the correlation among different coordinates. We use $\mathcal{H}_{i}$ to denote a collection of coordinates which are called "neighborhoods" of coordinate $i$. That is, $\mathcal{H}_{i} \subseteq\{1, \ldots, d\}$. We also assume $i \in \mathcal{H}_{i}$. Although the definition of the set $\mathcal{H}_{i}$ is quite arbitrary, we expect that $j \in \mathcal{H}_{i}$ implies the coordinates $i$ and $j$ are correlated even conditional on all other coordinates. This idea of "neighborhoods" become clearer if the target distribution comes from a model which can be written as a probabilistic graphical model [33]. For a graphical model, it is
convenient to define the "neighborhood" $j \in \mathcal{H}_{i}$ if there is an edge between nodes $i$ and $j$. In this definition, clearly $j \notin \mathcal{H}_{i}$ implies that the two coordinates $i$ and $j$ are conditional independent given all the other $d-2$ coordinates.

### 3.1. Optimal scaling for maximizing ESJD

Suppose $\left\{F_{d}\right\}$ is a sequence of "sets of typical states" and $\left\{\mathcal{H}_{i}\right\}$ are collections of "neighborhoods" for each coordinate. Throughout the paper, we assume $\sup _{i \in\{1, \ldots, d\}}\left|\mathcal{H}_{i}\right|<l_{d}$ where $l_{d}=o(d)$.

Remark 3.5. For graphical models, if we define $\mathcal{H}_{i}$ as the collection of nodes that is directly connected to $i$ by an edge, then $l_{d}=o(d)$ rules out "dense graphs" for which $l_{d} \propto d$. $\triangleleft$

Now we introduce the first assumption (A1) on the target $\pi^{d}$.

$$
\begin{equation*}
\sup _{(i, j): j \notin \mathcal{H}_{i}} \sup _{x^{d} \in F_{d}^{+}} \frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}}=o(1), \quad \sup _{(i, j): j \in \mathcal{H}_{i}} \sup _{x^{d} \in F_{d}^{+}} \frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}}=o\left(\sqrt{d / l_{d}}\right) . \tag{A1}
\end{equation*}
$$

Remark 3.6. For graphical models, if node $i$ is not directly connected to node $j$, we always have $\frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}}=0$. Therefore, in order to make (A1) hold, it suffices to check for each edge of the graph, say $(i, j)$, that $\frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}}=o\left(\sqrt{d / l_{d}}\right)$. Since we have assumed $l_{d}=o(d)$, this is a very weak condition. For example, (A1) holds for all graphical models with bounded second partial derivatives. $\triangleleft$

Next, we denote the conditional density of the $i$ th and $j$ th coordinates, given all the other coordinates fixed, by $\pi_{i, j \mid-i-j}:=\pi^{d}\left(x_{i}, x_{j} \mid x_{-i-j}\right)$ where $x_{-i-j}$ with $i<j$ denotes all coordinates of $x^{d}$ other than the $i$ th, and $j$ th coordinates, i.e.

$$
x_{-i-j}:=\left(x_{1}, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{d}\right)
$$

Note that $\pi_{i, j \mid-i-j}$ is a probability measure in $\mathbb{R}^{2}$. Then we introduce the next assumption (A2) on the target as follows.

$$
\begin{equation*}
\sup _{(i, j): j \notin \mathcal{H}_{i}\left\{x_{-i-j}: x^{d} \in F_{d}\right\}} \int \frac{\partial^{2} \pi_{i, j \mid-i-j}}{\partial x_{i}^{2}} \frac{\partial^{2} \pi_{i, j \mid-i-j}}{\partial x_{j}^{2}} \frac{1}{\pi_{i, j \mid-i-j}} \mathrm{~d} x_{i} \mathrm{~d} x_{j}=o(1) . \tag{A2}
\end{equation*}
$$

Remark 3.7. The assumption (A2) is very weak, since it is only to require that the target has a "flat tail". To see this, consider the target distribution $\pi^{d}$ has the special i.i.d. product form of Eq. (1), then (A2) reduces to

$$
\begin{equation*}
\int \frac{\partial^{2} f\left(x_{i}\right) f\left(x_{j}\right)}{\partial x_{i}^{2}} \frac{\partial^{2} f\left(x_{i}\right) f\left(x_{j}\right)}{\partial x_{j}^{2}} \frac{1}{f\left(x_{i}\right) f\left(x_{j}\right)} \mathrm{d} x_{i} \mathrm{~d} x_{j}=\left(\int \frac{\mathrm{d}^{2} f(x)}{\mathrm{d} x^{2}} \mathrm{~d} x\right)^{2}=0 \tag{10}
\end{equation*}
$$

when $f$ has a "flat tail" so that $\frac{\mathrm{d} f(x)}{\mathrm{d} x} \rightarrow 0$ when $|x| \rightarrow \infty$. Similarly, for graphical models, if there is no edge between $i$ and $j$, then when $\pi^{d}$ has "flat tail" we have $\int \frac{\partial^{2} \pi_{i, j \mid-i-j}}{\partial x_{i}^{2}} \frac{\partial^{2} \pi_{i, j \mid-i-j}}{\partial x_{j}^{2}} \frac{1}{\pi_{i, j \mid-i-j}} \mathrm{~d} x_{i} \mathrm{~d} x_{j}=0$.

The next assumption is about conditions on the third partial derivatives.

$$
\begin{align*}
& \sup _{(i, j): j \notin \mathcal{H}_{i} x^{d} \in \mathbb{R}^{d}} \frac{\sup ^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2} \partial x_{j}}=o(1), \quad \sup _{(i, j): j \in \mathcal{H}_{i}} \sup _{x^{d} \in \mathbb{R}^{d}} \frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2} \partial x_{j}}=o\left(d / l_{d}\right), \\
& \sup _{i} \sup _{x^{d} \in \mathbb{R}^{d}} \frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{3}}=o\left(d^{1 / 2}\right), \quad \sum_{i \neq j \neq k}\left(\left.\sup _{x^{d} \in \mathbb{R}^{d}} \frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j} \partial x_{k}} \right\rvert\,\right)=o\left(d^{3 / 2}\right) . \tag{A3}
\end{align*}
$$

Remark 3.8. We consider graphical models that satisfy (A3). The first three equations of (A3) are similar to (A1) and they hold for all graphical models with bounded third partial derivatives. Recall that, in graph theory, a $n$-clique of a graph is a fully-connected subset of nodes of the graph with cardinality $n$. The last equation of (A3) then involves the number of 3 -cliques in the graph. Note that for many realistic hierarchical models, there are no 3-cliques for the corresponding graphs, which implies $\sum_{i \neq j \neq k}\left|\frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j} \partial x_{k}}\right|=0$. Even for the worst case, considering a graph that has $d$ nodes and each has $l_{d}$ neighbors, since there are $d l_{d} / 2$ links, the number of 3-cliques is at most $\binom{l_{d}}{2} d / 3=\mathcal{O}\left(l_{d}^{2} d\right)$. Therefore, (A3) holds for any graphical model with $l_{d}=o\left(d^{1 / 4}\right)$ and bounded third partial derivatives. $\triangleleft$

The next assumption is the last assumption before our first main result. We first define a quantity which measures the "roughness" of $\log \pi^{d}$.

$$
\begin{equation*}
I_{d}\left(x^{d}\right):=\frac{1}{d} \sum_{i=1}^{d}\left(\frac{\partial}{\partial x_{i}} \log \pi^{d}\left(x^{d}\right)\right)^{2} \tag{11}
\end{equation*}
$$

Similarly, we can consider $I_{d}\left(X^{d}\right)$ where $X^{d} \sim \pi^{d}$ as a random variable. Later we will see that it turns out that $I_{d}\left(X^{d}\right)$ is a key quantity for optimal scaling results. Assumption (A4) is as follows.

There exists $\alpha$ with $0<\alpha<1 / 2$ such that

$$
\begin{equation*}
\sup _{i} \sup _{x^{d} \in F_{d}^{(i)}} \frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}}=\mathcal{O}\left(d^{\alpha}\right), \quad \sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)=o\left(d^{1 / 2-\alpha}\right), \quad \sup _{x^{d} \in F_{d}^{+}} 1 / I_{d}\left(x^{d}\right)=\mathcal{O}\left(d^{\alpha / 2}\right) . \tag{A4}
\end{equation*}
$$

Remark 3.9. For (A4), the first two conditions do not even require $\pi^{d}$ and the first partial derivative of $\log \pi^{d}$ to be bounded. Thus, they are quite weak. For the last condition, although the mode of $\pi^{d}$ is ruled out from $F_{d}^{+}$, the condition can hold as long as $\sup _{i} \sup _{x^{d} \in F_{d}^{(i)}} \frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}}=\mathcal{O}\left(d^{\alpha / 2}\right)$ and $I_{d}\left(X^{d}\right)$ is tight. That is, $\forall 0<\epsilon<1$, there exists $K_{\epsilon}>0$ such that $\mathbb{P}\left(I_{d}\left(X^{d}\right)>K_{\epsilon}\right)<(1-\epsilon)$. To see this, one can choose $F_{d}$ using the tightness such that $\sup _{x^{d} \in F_{d}} 1 / I_{d}\left(x^{d}\right)=\mathcal{O}\left(d^{\alpha / 2}\right)$. Then we can replace $F_{d}$ by $F_{d}^{+}$since $\inf _{x^{d} \in F_{d}} I_{d}\left(x^{d}\right)-\inf _{x^{d} \in F_{d}^{+}} I_{d}\left(x^{d}\right)=\mathcal{O}\left(d^{\alpha / 2}(\log d)^{1 / 2} d^{-1 / 2}\right)=o\left(d^{-1 / 4}\right)=o\left(d^{-\alpha / 2}\right)$. Note that $I_{d}\left(X^{d}\right)$ being tight is a very reasonable assumption, since if $I_{d}\left(X^{d}\right)$ is not tight, the target $\pi^{d}$ becomes "flat" at almost every state $x^{d}$. $\triangleleft$

We are now ready to present our first main result using the assumptions (A1), (A2), (A3), and (A4). We establish the following results on asymptotic ESJD and asymptotic acceptance rate.

Theorem 3.10 (Asymptotic ESJD and Acceptance Rate). Suppose $\pi^{d}$ satisfies (A1), (A2), (A3), and (A4), then as $d \rightarrow \infty$, we have

$$
\begin{align*}
& \left|\operatorname{ESJD}(d)-2 \frac{d \ell^{2}}{d-1} \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right| \rightarrow 0,  \tag{12}\\
& \left|\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y^{d}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)-2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right| \rightarrow 0, \tag{13}
\end{align*}
$$

where the expectation over $Y^{d}$ is taken for $Y^{d} \sim \mathcal{N}\left(x^{d}, \frac{\ell^{2}}{d-1} I\right)$ for given $X^{d}=x^{d}$.
Proof. See Appendix A.

Since the assumptions required by Theorem 3.10 are very mild, the result of Theorem 3.10 holds for a large class of realistic MCMC models. As an example, we give a class of graphical models that all conditions (A1), (A2), (A3), and (A4) hold. Therefore, the asymptotic ESJD and acceptance rate by Theorem 3.10 hold for this class of graphical models. We will further discuss realistic MCMC models later in Sections 4.1 and 4.2.

We give a simple criterion that the assumptions (A1), (A2), (A3), and (A4) hold. More discussions and examples are delayed to Section 4.

Corollary 3.11. If a graphical model satisfies (i) either each node has at most $l_{d}=o\left(d^{1 / 4}\right)$ links or the number of 3-cliques of the graph is o( $d^{3 / 2}$ ); (ii) $I_{d}\left(X^{d}\right)$ is tight; (iii) $\pi^{d}$ has bounded density and $\log \pi^{d}$ has up to the third bounded partial derivatives, then the assumptions (A1), (A2), (A3), and (A4) hold. Therefore, the asymptotic ESJD and acceptance rate results by Theorem 3.10 hold.

Proof. First, the assumption (A1) holds when second partial derivatives of $\log \pi^{d}$ are bounded. Next, the assumption (A2) automatically holds for graphical models. Furthermore, $l_{d}=o\left(d^{1 / 4}\right)$ implies that the number of 3-cliques is $o\left(d^{3 / 2}\right)$. Then one can easily verify that the assumption (A3) holds using the fact that the third partial derivatives of $\log \pi^{d}$ are bounded. Finally, the assumption (A4) holds since $I_{d}\left(X^{d}\right)$ is tight.

Note that Theorem 3.10 suggests that under mild conditions on the target distribution, the expected acceptance rate

$$
\begin{equation*}
\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y^{d}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right) \rightarrow 2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right] \tag{14}
\end{equation*}
$$

Therefore, we can define asymptotic acceptance rate as a function of $\ell$ as follows.
Definition 3.12 (Asymptotic Acceptance Rate). The asymptotic acceptance rate function is defined by

$$
\begin{equation*}
a(\ell):=2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right] . \tag{15}
\end{equation*}
$$

The next theorem shows that if the target distribution satisfies (A1)-(A4), then if we maximize the asymptotic ESJD, the resulting asymptotic acceptance rate is no larger than 0.234 .

Theorem 3.13. Defining the optimal parameter for maximizing the asymptotic ESJD by $\hat{\ell}$, i.e.

$$
\begin{equation*}
\hat{\ell}:=\arg \max _{\ell} h(\ell), \quad h(\ell):=2 \ell^{2} \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right], \tag{16}
\end{equation*}
$$

then we have $a(\hat{\ell}) \leq 0.234$ (to three decimal places).
Proof. We follow the arguments in [71, Lemma 5.1.4]. First, it can be verified by taking the second derivatives of $h(\ell)$ with respect to $\ell$ that the maximum of $h(\ell)$ is achieved at $\ell$ such that $\frac{\partial h(\ell)}{\partial \ell}=0$. Therefore, the optimal $\hat{\ell}$ satisfies

$$
\begin{equation*}
2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]=\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2} \Phi^{\prime}\left(-\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right] \tag{17}
\end{equation*}
$$

Therefore, the asymptotic acceptance rate

$$
\begin{equation*}
a(\hat{\ell})=\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2} \Phi^{\prime}\left(-\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]=\mathbb{E}_{X^{d} \sim \pi^{d}}\left[-\Phi^{-1}(V) \Phi^{\prime}\left(\Phi^{-1}(V)\right)\right], \tag{18}
\end{equation*}
$$

where $V:=\Phi\left(-\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)$. By Sherlock [65], the function $-\Phi^{-1}(x) \Phi^{\prime}\left(\Phi^{-1}(x)\right)$ is a concave function for any $x \in(0,1)$. Therefore, we have

$$
\begin{equation*}
a(\hat{\ell})=\mathbb{E}_{X^{d} \sim \pi^{d}}\left[-\Phi^{-1}(V) \Phi^{\prime}\left(\Phi^{-1}(V)\right)\right] \leq-\Phi^{-1}\left[\mathbb{E}_{X^{d} \sim \pi^{d}}(V)\right] \Phi^{\prime}\left[\Phi^{-1}\left(\mathbb{E}_{X^{d} \sim \pi^{d}}(V)\right)\right] \tag{19}
\end{equation*}
$$

Defining $m:=-\Phi^{-1}\left[\mathbb{E}_{X^{d} \sim \pi^{d}}(V)\right]$, we can then write $a(\hat{\ell})=2 \Phi(-m) \leq m \Phi^{\prime}(-m)$. Finally, it suffices to show that $2 \Phi(-m) \leq m \Phi^{\prime}(-m)$ implies $2 \Phi(-m) \leq 0.234$ (to three decimal places). Note that the function $x^{2} \Phi(-\bar{x})$ is maximized at $\hat{m}$ such that $2 \Phi(-\hat{m})=\hat{m} \Phi^{\prime}(-\hat{m}) \approx 0.234$. By Tawn [71, Lemma 5.1.4], the function $2 \Phi(-x)-x \Phi^{\prime}(-x)$ is positive for $x<\hat{m}$ and negative for $x>\hat{m}$. Therefore, $2 \Phi(-m) \leq m \Phi^{\prime}(-m)$ implies that $m>\hat{m}$. Since $\Phi(-x)$ is monotonically decreasing with $x$, we have $\bar{a}(\hat{\ell})=2 \Phi(-m) \leq 2 \Phi(-\hat{m}) \approx 0.234$.

The next result is our main result for optimal scaling by maximizing ESJD. Defining the following WLLN condition for the target $\pi^{d}$ :

$$
\begin{equation*}
I_{d}\left(X^{d}\right)-\bar{I}_{d} \rightarrow 0 \quad \text { in probability } \tag{A5}
\end{equation*}
$$

where $X^{d} \sim \pi^{d}$ and $\bar{I}_{d}:=\mathbb{E}_{X^{d} \sim \pi^{d}}\left[I_{d}\left(X^{d}\right)\right]$, we show that if the target distribution $\pi^{d}$ satisfies (A1), (A2), (A3), (A4), and the WLLN assumption in (A5), then the acceptance rate 0.234 is asymptotically optimal.

Theorem 3.14 (Optimal Scaling for Maximizing ESJD). Suppose the target distribution $\pi^{d}$ satisfies (A1), (A2), (A3), (A4), and (A5). Then the asymptotic optimal acceptance rate $a(\hat{\ell}) \approx 0.234$ (to three decimal places).

Proof. By convexity of the function $\Phi(-x)$ when $x \geq 0$, we can immediately obtain a lower bound

$$
\begin{equation*}
\ell^{2} \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right] \geq \ell^{2}\left[\Phi\left(-\frac{\ell \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I_{d}\left(X^{d}\right)}\right]}{2}\right)\right] \tag{20}
\end{equation*}
$$

Under (A5), this lower bound is asymptotically tight. Therefore, as $d \rightarrow \infty$, according to [54], we have (to two decimal places)

$$
\begin{equation*}
\hat{\ell} \rightarrow \frac{2.38}{\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I_{d}\left(X^{d}\right)}\right]}, \quad h(\hat{\ell}) \rightarrow \frac{1.3}{\left(\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I_{d}\left(X^{d}\right)}\right]\right)^{2}} . \tag{21}
\end{equation*}
$$

The acceptance rate which maximizing the asymptotic ESJD is

$$
\begin{align*}
a(\hat{\ell}) & =2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\hat{\ell} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right] \rightarrow 2 \Phi\left(-\frac{\hat{\ell} \mathbb{E}_{X^{d} \sim \pi^{d}} \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)  \tag{22}\\
& \approx 2 \Phi\left(-\frac{2.38}{\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I_{d}\left(X^{d}\right)}\right]} \frac{\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I_{d}\left(X^{d}\right)}\right]}{2}\right)=2 \Phi(-1.19) \approx 0.234 . \tag{23}
\end{align*}
$$

Remark 3.15. Comparing the results of Theorems 3.13 and 3.14, it is clear that the "roughness" of $\pi^{d}, I_{d}\left(X^{d}\right)$, is the key quantity which determines the optimal acceptance rate $a(\hat{\ell}) \leq 0.234$ when only the tightness of $I_{d}\left(X^{d}\right)$ can be verified, or $a(\hat{\ell}) \approx 0.234$ when the concentration of $I_{d}\left(X^{d}\right)$ as defined in (A5) can be verified. We will later demonstrate how to verify (A5) for some realistic MCMC models in Sections 4.1 and 4.2. $\triangleleft$

### 3.2. Optimal scaling via diffusion limits

In this subsection, we consider sufficient conditions on $\pi^{d}$ for establishing weak convergence of diffusion limits. As we discussed before, establishing such results gives stronger guarantee for optimal scaling than maximizing ESJD. However, it also requires stronger conditions on the target distribution. As we will see in the following, we need to strengthen assumptions (A2), (A3), (A4), (A5) and add one more assumption (A6).

We first strengthen (A2) to a new assumption (A2+) as follows.

$$
\begin{equation*}
\sum_{i=1}^{d} \sum_{j=1}^{d} \sum_{k=1}^{d} \int\left(\frac{\partial^{2} \pi^{d}}{\partial x_{i}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d}=\mathcal{O}\left(d^{2-\delta}\right) \tag{A2+}
\end{equation*}
$$

for some $\delta>0$.
Remark 3.16. The new assumption (A2+) is stronger than (A2) but is still very mild. To see this, we consider graphical models as examples. For graphical models with $d$ nodes each with $\mathcal{O}\left(l_{d}\right)$ links, there are at most $\mathcal{O}\left(d l_{d}^{2}\right) 3$-cliques. Therefore, (A2+) holds for any graphical model with $l_{d}=o\left(d^{1 / 2-\delta}\right)$ and bounded second partial derivatives of $\log \pi^{d}$. Note that this is only for the worst case, as many realistic graphical models do not have 3-cliques.

Next, we slightly strengthen (A3) and (A4) to (A3+) and (A4+).

$$
\begin{align*}
& \sup _{(i, j): j \notin \mathcal{H}_{i}} \sup _{x^{d} \in \mathbb{R}^{d}} \frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2} \partial x_{j}}=o(1), \quad \sup _{(i, j): j \in \mathcal{H}_{i}} \sup _{x^{d} \in \mathbb{R}^{d}} \frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2} \partial x_{j}}=o\left(\sqrt{d / l_{d}}\right), \\
& \sum_{i \neq j \neq k}\left(\sup _{x^{d} \in \mathbb{R}^{d}}\left|\frac{\partial^{3} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j} \partial x_{k}}\right|\right)=o\left(d^{3 / 2}\right) . \tag{A3+}
\end{align*}
$$

Suppose there exists $0<\alpha<1 / 2$ that

$$
\begin{align*}
& \sup _{i} \sup _{x^{d} \in F_{d}^{(i)}} \frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2}}=o\left(d^{\alpha}\right), \quad \sup _{i} \sup _{x^{d} \in F_{d}^{(i)}} \frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}}=\mathcal{O}\left(d^{\alpha / 2}\right),  \tag{A4+}\\
& \sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)=o\left(d^{1 / 2-\alpha}\right), \quad \sup _{x^{d} \in F_{d}^{+}} 1 / I_{d}\left(x^{d}\right)=\mathcal{O}\left(d^{\alpha / 4}\right) .
\end{align*}
$$

Furthermore, we strengthen the WLLN condition (A5) to the following (A5+).

$$
\begin{equation*}
\sup _{x^{d} \in F_{d}^{+}}\left|I_{d}\left(x^{d}\right)-\bar{I}\right| \rightarrow 0 \tag{A5+}
\end{equation*}
$$

where $\bar{I}:=\lim _{d \rightarrow \infty} \bar{I}_{d}$ exists.
Remark 3.17. (A3+) is only slightly stronger than (A3) on the rates. (A4+) also includes a new condition on the rate of $\frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}^{2}}$ which is quite weak. (A5+) requires any sequence $\left(x^{1}, x^{2}, \ldots, x^{d}, \ldots\right)$ where $x^{i} \in F_{i}^{+}$converges to the same limit $\bar{I}$, so it is (slightly) stronger than WLLN condition in (A5). It will become clear in the proof of Theorem 3.19 that (A5+) is to ensure the speed measure of the diffusion process $h(\ell)$ does not depend on the state $x^{d}$. $\triangleleft$

Finally, we define a new assumption (A6) on the target distribution. Roughly speaking, the new assumption is to require the first coordinate of $\pi^{d}$ is asymptotically independent with the rest.

$$
\begin{equation*}
\lim _{d \rightarrow \infty} \sup _{x^{d} \in F_{d}^{+}}\left|\frac{\mathrm{d}}{\mathrm{~d} x_{1}}\left[\log \pi^{d}\left(x_{1} \mid x_{-1}\right)-\log \tilde{\pi}\left(x_{1}\right)\right]\right|=0 \tag{A6}
\end{equation*}
$$

where $x_{-1}:=\left(x_{2}, \ldots, x_{d}\right), \tilde{\pi}$ is a one-dimensional density and $(\log \tilde{\pi})^{\prime}$ is Lipschitz continuous.
Remark 3.18. Note that (A6) is a strong condition, which may not be satisfied for many realistic MCMC models. However, it might be necessary in order to get a one-dimensional diffusion limit for the first coordinate. In the proof of the optimal scaling via diffusion limits result in Theorem 3.19, the assumption (A6) is to ensure the SDE for the first coordinate $x_{1}$ does not depend on the values of other coordinates. Furthermore, although we do not pursue in this paper, if in (A6) we instead assume not just the first component but a finite collection of components are asymptotically independent from the rest, a version of weak convergence to multi-dimensional diffusion limits could be obtained following similar arguments as the proof of the one-dimensional diffusion limit case in Theorem 3.19. $\triangleleft$

Now we are ready for the main result of optimal scaling via diffusion limits, which is given in Theorem 3.19. We show that, even though different coordinates of the Markov chain are not
independent nor even individually Markovian, the sped-up first-coordinate process converges to a limiting diffusion limit under much more general conditions on the target distribution. Comparing with the assumptions in Theorem 3.14, the new sufficient conditions for diffusion limits include strengthening (A2) to (A2+), (A3) and (A4) to (A3+) and (A4+), (A5) to (A5+), and adding (A6). We also require slightly stronger condition on the sequence of "sets of typical states" $\left\{F_{d}\right\}$.

Theorem 3.19 (Optimal Scaling via Diffusion Limits). Suppose the sequence $\left\{F_{d}\right\}$ satisfies $\pi^{d}\left(F_{d}^{c}\right)=\mathcal{O}\left(d^{-1-\delta}\right)$ for some $\delta>0$, the target distribution $\pi^{d}$ satisfies (A1), (A2+), (A3+), (A4+), (A5+), and (A6), then for $U^{d}(t):=X_{1}^{d}(\lfloor d t\rfloor)$, as $d \rightarrow \infty$, we have $U^{d} \Rightarrow U$, where $\Rightarrow$ denotes weak convergence in Skorokhod topology, and $U$ satisfies the Langevin SDE

$$
\begin{equation*}
\mathrm{d} U(t)=(h(\ell))^{1 / 2} \mathrm{~d} B(t)+h(\ell) \frac{\tilde{\pi}^{\prime}(U(t))}{2 \tilde{\pi}(U(t))} \mathrm{d} t \tag{24}
\end{equation*}
$$

where $h(\ell):=2 \ell^{2} \Phi(-\ell \sqrt{\bar{I}} / 2)$ is the speed measure for the diffusion process.
Proof. See Appendix C.
Remark 3.20. Note that Theorem 3.19 allows dependent coordinates on the target distribution, which is much more general than the product i.i.d. condition. The only strong assumption is (A6) which requires the first coordinate is asymptotically independent with other coordinates.

Next, we present another result with slightly stronger conditions, which allows the RWM algorithm to start at a fixed state. This stronger convergence result later allows us to establish a complexity bound for the RMW algorithm in Section 3.3 Let $X^{d}=\left\{X^{d}(t), t \geq 0\right\}$ for $d \in \mathbb{N}$ be the RWM processes defined earlier. Without loss of generality, suppose $\left\{X^{d}, d=1,2, \ldots\right\}$ are defined in a common measurable metric space $\left(\mathbb{R}^{\infty}, \mathcal{F}, \rho\right)$ as independent processes.

Theorem 3.21 (Optimal Scaling Via Diffusion Limits with Fixed Starting State). Suppose $X_{1}^{d}$ converges weakly in the Skorokhod topology as $d \rightarrow \infty$ to a càdlàg process $X_{1}^{\infty}$. Moreover, assume these processes $\left\{X^{d}, d=1,2, \ldots\right\}$ all have the same marginal stationary distribution $\pi_{1}$ for the first coordinate and that the first coordinate of $X^{\infty}$ converges weakly to $\pi_{1}$. Suppose the sequence $\left\{F_{d}\right\}$ satisfies $\pi^{d}\left(F_{d}^{c}\right)=\mathcal{O}\left(d^{-2-\delta}\right)$ for some $\delta>0$, the target distribution $\pi^{d}$ satisfies (A1), ( $\mathrm{A} 3+$ ), ( $\mathrm{A} 4+$ ), ( $\mathrm{A} 5+$ ), and ( A 6 ). We strengthen ( $\mathrm{A} 2+$ ) to the following condition

$$
\sum_{i, j, k, l, m \in\{2, \ldots, d\}} \int\left(\frac{\partial^{2} \pi_{-1}}{\partial x_{i}^{2}} \cdot \frac{\partial^{2} \pi_{-1}}{\partial x_{j}^{2}} \cdot \frac{\partial^{2} \pi_{-1}}{\partial x_{k}^{2}} \cdot \frac{\partial^{2} \pi_{-1}}{\partial x_{l}^{2}} \cdot \frac{\partial^{2} \pi_{-1}}{\partial x_{m}^{2}}\right)\left(\frac{1}{\pi_{-1}}\right)^{5} \pi^{d} \mathrm{~d} x^{d}=\mathcal{O}\left(d^{3-6 \delta}\right) .(\mathrm{A} 2++)
$$

Then as $d \rightarrow \infty$, we have ${ }_{x} U^{d} \Rightarrow{ }_{x} U$, where ${ }_{x} U^{d}(t):=\left(X_{1}^{d}(\lfloor d t\rfloor) \mid X_{1}^{d}(0)=x\right)$ is the first coordinate of the RWM algorithm sped up by a factor of $d$, conditional on starting at the state $x$, and ${ }_{x} U$ is the limiting ergodic Langevin diffusion $U$ in Eq. (24) also conditional on starting at $x$.

Proof. See Appendix D.

Remark 3.22. The new assumption (A2++) is stronger than (A2+) but is still not strong. To see this, for graphical models with $d$ nodes, each with $\mathcal{O}\left(l_{d}\right)$ links, we have at most $\mathcal{O}\left(d l_{d}^{2}\right) 3$ cliques. Under flat tail assumptions, at most $\mathcal{O}\left(d^{2} l_{d}^{3}\right)$ terms in the summation in (A2++) is not zero. Therefore, (A2++) holds for any graphical model with $l_{d}=o\left(d^{1 / 3-2 \delta}\right)$ and bounded second partial derivatives of $\log \pi^{d}$. Note that this is only for the worst case, as many realistic graphical models do not have 3 -cliques. $\triangleleft$

### 3.3. Complexity bounds via diffusion limits

In the following, by combining Theorem 3.21 and Proposition 2.3, we present a complexity bound for the RWM algorithm which holds for much more general target distributions comparing with [58]. More specifically, if the target distribution satisfies the conditions given in Theorem 3.21 which allows dependent coordinates of the target distribution, the RWM algorithm in $d$ dimensions takes $\mathcal{O}(d)$ iterations to converge to stationarity.

Corollary 3.23 (Complexity Bound for RWM Algorithms). Under the conditions of Theorem 3.21, for any $\epsilon>0$, there exists $D<\infty$ and $T<\infty$, such that

$$
\begin{equation*}
\mathbb{E}_{X_{1}^{d}(0) \sim \pi_{1}}\left\|\mathcal{L}_{X_{1}^{d}(0)}\left(X_{1}^{d}(\lfloor d t\rfloor)\right)-\pi_{1}\right\|_{K R}<\epsilon, \quad \forall t \geq T, d \geq D, \tag{25}
\end{equation*}
$$

where $\pi_{1}$ denotes the marginal stationary distribution of the first coordinate.
Proof. The result directly comes from Proposition 2.3 and Theorem 3.21.

## 4. Examples and applications

In this section, we further discuss examples and applications of the main results in Section 3. We first discuss in Section 4.1 on verifying the assumptions of Theorem 3.14 for realistic MCMC models. We have explained in Remarks 3.6-3.9 that (A1), (A2), (A3), and (A4) are typically very weak conditions and they hold for some classes of graphical models. However, as discussed in Remark 3.15, the assumption (A5) may need to be verified case by case. Particularly, in order to satisfy (A5), we may need to make additional assumptions on the observed data. Fortunately, we show by a simple Gaussian example in Example 4.1 that, in some cases, (A5) can be easily verified without any further assumptions. Then, in Section 4.2, we extend the simple Gaussian example in Example 4.1 to a more realistic MCMC model in Example 4.5 and show it satisfies all the assumptions required by Theorem 3.14. Thus, the acceptance rate 0.234 is indeed asymptotically optimal for this realistic MCMC model.

### 4.1. Discussions on Theorem 3.14

The optimal scaling result for maximizing ESJD in Theorem 3.14 requires one to verify that the target distribution satisfies (A1), (A2), (A3), (A4), and (A5). We discuss how to verify the conditions on the target distribution required by Theorem 3.14 in practice. We explain that (A1), (A2), (A3) and (A4) are quite mild and usually easy to be verified. Therefore, we usually only need to focus on the WLLN condition in (A5), which might be difficult to check in practice. Throughout this subsection, we demonstrate verification of all the assumptions by a simple Gaussian example, which can be seen as a simplified version of typical Bayesian hierarchical models.

Example 4.1 (A Gaussian Example). Consider a simple Gaussian MCMC model

$$
\begin{align*}
Y_{i j} \mid \theta_{i j} & \sim \mathcal{N}\left(\theta_{i j}, 1\right), \quad i, j \in\{1, \ldots, n\} \\
\theta_{i j} \mid \mu_{j} & \sim \mathcal{N}\left(\mu_{j}, 1\right), \quad i \in\{1, \ldots, n\}  \tag{26}\\
\mu_{j} \mid v & \sim \mathcal{N}(v, 1) \\
v & \sim \text { flat prior on } \mathbb{R},
\end{align*}
$$

where $\left\{Y_{i j}\right\}_{i, j=1}^{n}$ are the observed data, and $x^{d}=\left(\nu,\left\{\mu_{j}\right\}_{j=1}^{n},\left\{\theta_{i j}\right\}_{i, j=1}^{n}\right)$ are parameters. Note that we have the number of parameters $d=n^{2}+n+1$ in this example. The target distribution (i.e. the posterior distribution) satisfies

$$
\begin{equation*}
\pi^{d}\left(x^{d}\right)=\mathbb{P}\left(x^{d} \mid\left\{Y_{i j}\right\}_{i, j=1}^{n}\right) \propto \prod_{j=1}^{n} \prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi}} e^{-\frac{\left(\mu_{j}-v\right)^{2}}{2}} \frac{1}{\sqrt{2 \pi}} e^{-\frac{\left(\theta_{i j}-\mu_{j}\right)^{2}}{2}} \frac{1}{\sqrt{2 \pi}} e^{-\frac{\left(Y_{i j}-\theta_{i j}\right)^{2}}{2}} . \tag{27}
\end{equation*}
$$

Note that the hyperparameters $v$ is conditionally independent given $\left\{\theta_{i j}\right\}$. Therefore, $v$ is only directly dependent with $n$ coordinates $\left\{\mu_{j}\right\}_{j=1}^{n}$. We can define the "neighborhoods" of $v$ using the collection of $\mu_{j}, j=1, \ldots, n$. Similarly, $\mu_{j}$ is directly dependent with $\nu$ and $\left\{\theta_{i j}\right\}_{i=1}^{n}$ and $\theta_{i j}$ is directly dependent with $\mu_{j}$. Therefore, if we choose the directly dependent coordinates as "neighborhoods", we have $l_{d}=n+1=\mathcal{O}\left(d^{1 / 2}\right)$.

### 4.1.1. Verifying (A1) to (A4)

First of all, the two conditions for $(i, j): j \neq \mathcal{H}_{i}$ in (A1) and (A3) hold trivially for graphical models. Furthermore, in Example 4.1, the parameter $v$ is conditional independent with all $\theta_{i j}$ and the corresponding conditional posterior distributions all have Gaussian tails, which implies (A2) holds for any pair of coordinates ( $\nu, \theta_{i j}$ ). Similarly, one can easily verify the assumption holds for other pairs of parameters.

Next, all the conditions on the third partial derivatives of $\log \pi^{d}$ hold, since there are no 3 -cliques. Moreover, in Example 4.1, we have $l_{d}=\mathcal{O}\left(d^{1 / 2}\right)$. The second partial derivative is $\mathcal{O}(1)$, and the density $\pi^{d}$ is bounded, so the following conditions hold without the need of choosing $\left\{F_{d}\right\}$ :

$$
\begin{equation*}
\sup _{(i, j): j \in \mathcal{H}_{i}} \sup _{x^{d} \in F_{d}^{+}} \frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}}=o\left(\sqrt{d / l_{d}}\right), \quad \sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)=o\left(d^{1 / 2-\alpha}\right) \tag{28}
\end{equation*}
$$

Finally, the last two conditions are almost immediately true once (A5) has been verified:

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}} \sup _{x^{d} \in F_{d}^{+}} \frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}}=\mathcal{O}\left(d^{\alpha}\right), \quad \sup _{x^{d} \in F_{d}^{+}} 1 / I\left(x^{d}\right)=\mathcal{O}\left(d^{\alpha / 2}\right) \tag{29}
\end{equation*}
$$

To see this, under (A5), we have $\frac{1}{d} \sum_{i=1}^{d}\left(\frac{\partial}{\partial x_{i}} \log \pi^{d}\left(x^{d}\right)\right)^{2} \rightarrow \bar{I}_{d}$. If $\bar{I}_{d} \rightarrow \bar{I}$ and $\bar{I}>0$, then we can select constant $K_{2}>0$ small enough such that $\bar{I}>K_{2} d^{-\alpha / 2}>0$ then $\bar{I}_{d}>K_{2} d^{-\alpha / 2}$ for all large enough $d$. Next, by choosing the typical set $F_{d}$ such that for any $x^{d} \in F_{d}^{+}$, we have $\frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}} \leq K_{1} d^{\alpha}, \quad I_{d}\left(x^{d}\right) \geq K_{2} d^{-\alpha / 2}$, where $K_{1}$ is a large enough constant. Then it suffices to check if $\left\{F_{d}\right\}$ is a valid sequence of typical sets such that $\pi^{d}\left(F_{d}\right) \rightarrow 1$. For Example 4.1, we have $X^{d}=\left(\nu,\left\{v_{j}\right\}_{j=1}^{n},\left\{\theta_{i j}\right\}_{i, j=1}^{n}\right)$. We will show later that (A5) holds such that under $X^{d} \sim \pi^{d}$ we have $\frac{1}{d} \sum_{i=1}^{d}\left(\frac{\partial}{\partial x_{i}} \log \pi^{d}\left(X^{d}\right)\right)^{2} \rightarrow 3$. For example, we can choose $K_{2}=0.01, K_{1}=100$,
and the typical set $F_{d}$ such that, for any $X^{d}=x^{d} \in F_{d}^{+}$, we have

$$
\begin{align*}
& I_{d}\left(x^{d}\right)>0.01 n^{-\alpha}, \quad \frac{\partial \log \pi^{d}}{\partial v}=n(\bar{\mu}-v) \leq 100 n^{2 \alpha},  \tag{30}\\
& \frac{\partial \log \pi^{d}}{\partial \mu_{j}}=(n+1)\left(\frac{\sum_{i} \theta_{i j}+v}{n+1}-\mu_{j}\right) \leq 100 n^{2 \alpha},  \tag{31}\\
& \frac{\partial \log \pi^{d}}{\partial \theta_{i j}}=2\left(\frac{Y_{i j}+\mu_{j}}{2}-\theta_{i j}\right) \leq 100 n^{2 \alpha}, \tag{32}
\end{align*}
$$

where $\alpha<1 / 2$ can be arbitrarily close to $1 / 2$. Observing that, under $X^{d} \sim \pi^{d}$, we have the following conditional distributions.

$$
\begin{align*}
& \theta_{i j} \mid Y_{i j}, \mu_{j} \quad \sim \text { indep. } \mathcal{N}\left(\frac{\mu_{j}+Y_{i j}}{2}, \frac{1}{2}\right), \quad i, j \in\{1, \ldots, n\}, \\
& \mu_{j} \mid \sum_{i} \theta_{i j}, v \sim^{\text {indep. }} \mathcal{N}\left(\frac{\sum_{i} \theta_{i j}+v}{n+1}, \frac{1}{n+1}\right), \quad i \in\{1, \ldots, n\},  \tag{33}\\
& v \left\lvert\, \bar{\mu} \sim \mathcal{N}\left(\bar{\mu}, \frac{1}{n}\right) .\right.
\end{align*}
$$

Then it can be easily verified that $\pi^{d}\left(F_{d}\right) \rightarrow 1$.

### 4.1.2. Verifying (A5)

One assumption of Theorem 3.14 that could be difficult to verify in practice is (A5). It requires the sequence of random variables $\left\{I_{d}\left(X^{d}\right)\right\}$ converge to a sequence of constants in probability. We feel this assumption has to be checked case by case and it is hard to get general sufficient condition for it to hold. For realistic MCMC models, this may require assumptions on the observed data so that the posterior distribution has certain "concentration" properties as $d \rightarrow \infty$.

Fortunately, for Example 4.1, we can verify that (A5) holds without any further assumption on the observed data $\left\{Y_{i j}\right\}$. Note that in Example 4.1, we have

$$
\begin{align*}
& \left(\frac{\partial \log \pi^{d}}{\partial v}\right)^{2}=\left(\sum_{j}\left(\mu_{j}-v\right)\right)^{2}=n^{2}(\bar{\mu}-v)^{2}  \tag{34}\\
& \left(\frac{\partial \log \pi^{d}}{\partial \mu_{j}}\right)^{2}=\left(\sum_{i}\left(\theta_{i j}-\mu_{j}\right)-\left(\mu_{j}-v\right)\right)^{2}=(n+1)^{2}\left(\frac{\sum_{i} \theta_{i j}+v}{n+1}-\mu_{j}\right)^{2},  \tag{35}\\
& \left(\frac{\partial \log \pi^{d}}{\partial \theta_{i j}}\right)^{2}=\left(\left(Y_{i j}-\theta_{i j}\right)-\left(\theta_{i j}-\mu_{j}\right)\right)^{2}=4\left(\frac{Y_{i j}+\mu_{j}}{2}-\theta_{i j}\right)^{2} \tag{36}
\end{align*}
$$

Hence, if suffices to show that, under $X^{d}=\left(\nu,\left\{\mu_{j}\right\}_{j=1}^{n},\left\{\theta_{i j}\right\}_{i, j=1}^{n}\right) \sim \pi^{d}$, the following three terms converges to some constants in probability or in distribution:

$$
\begin{align*}
& \frac{1}{d}\left(\frac{\partial \log \pi^{d}}{\partial v}\right)^{2}=\frac{n^{2}}{n^{2}+n+1}(\bar{\mu}-v)^{2}  \tag{37}\\
& \frac{1}{d} \sum_{j}\left(\frac{\partial \log \pi^{d}}{\partial \mu_{j}}\right)^{2}=\frac{(n+1)^{2}}{n^{2}+n+1} \sum_{j}\left(\frac{\sum_{i} \theta_{i j}+v}{n+1}-\mu_{j}\right)^{2} \tag{38}
\end{align*}
$$

$$
\begin{equation*}
\frac{1}{d} \sum_{i j}\left(\frac{\partial \log \pi^{d}}{\partial \theta_{i j}}\right)^{2}=\frac{4}{d} \sum_{i j}\left(\frac{Y_{i j}+\mu_{j}}{2}-\theta_{i j}\right)^{2} \tag{39}
\end{equation*}
$$

We have observed that the target distribution $\pi^{d}$ has conditional independence structure in Eq. (33), which immediately leads to

$$
\begin{equation*}
(\bar{\mu}-v)^{2} \rightarrow^{\mathbb{P}} 0, \quad \sum_{j}\left(\frac{\sum_{i} \theta_{i j}+v}{n+1}-\mu_{j}\right)^{2} \rightarrow^{\mathbb{P}} 1, \quad \frac{1}{d} \sum_{i j}\left(\frac{Y_{i j}+\mu_{j}}{2}-\theta_{i j}\right)^{2} \rightarrow^{\mathbb{P}} \frac{1}{2} . \tag{40}
\end{equation*}
$$

Therefore, (A5) is satisfied.
Overall, we have checked all the assumptions of Theorem 3.14 for our simple Gaussian example. Therefore, by Theorem 3.14, we have the following optimal scaling result for Example 4.1.

Proposition 4.2. The optimal scaling for Example 4.1 by maximizing ESJD is to choose (to two decimal places) $\hat{\ell} \approx \frac{2.38}{\mathbb{E}_{X^{d} \sim \pi^{d}}\left[\sqrt{I\left(X^{d}\right)}\right]} \rightarrow \frac{2.38}{\sqrt{3}} \approx 1.37$ and the corresponding asymptotic acceptance rate is (to three decimal places) 0.234.

### 4.2. Optimal scaling of a realistic MCMC model

We first discuss sufficient conditions for two more classes of graphical models. In Proposition 4.3, we give sufficient conditions for the first equation of (A1), (A2), and the first equation of (A3) to hold for one particular class of graphical models. In Proposition 4.4, we give sufficient conditions for (A5) to hold for one specific class of graphical models.

First, we consider the class of graphical models represented by the factor graphs:

$$
\begin{equation*}
\pi^{d}\left(x^{d}\right) \propto \prod_{k=1}^{K_{d}} \psi_{k}\left(\left\{x_{i}: i \in C_{k}\right\}\right) \tag{41}
\end{equation*}
$$

where $C_{k}$ are cliques, $\psi_{k}$ are potentials, $K_{d}$ denotes the number of potentials.
Proposition 4.3. For the class of graphical models represented by Eq. (41). Let $m_{d}$ denote the maximum number of cliques a coordinate can belong to. If all the potentials $\psi_{k}$ have "flat tails" in the sense that for all $k$ we have $\frac{\partial \psi_{k}}{\partial x_{i}} \rightarrow 0$ as $\left|x_{i}\right| \rightarrow \infty$ for all $i \in C_{k}$, and the cardinality of $C_{k}$ satisfies $\sup _{k}\left|C_{k}\right|=o\left(d / m_{d}\right)$, then the first equation in (A1), (A2), and the first equation in (A3) hold.

Next, we consider Bayesian hierarchical modeling where $K$ denotes the number of "layers" or "stages" of the model. We use $\theta^{(k)}, k=1, \ldots, K$ to denote the parameter vector with length $n_{k}$ for the $k$ th layer, where $\theta^{(k)}:=\left(\theta_{1}^{(k)}, \ldots, \theta_{n_{k}}^{(k)}\right)$. We consider the special structure of the graphical model such that $\theta^{(k)}$ is only connected to $\theta^{(k-1)}$ and $\theta^{(k+1)}$. Using factor graphs, let $x^{d}=\left(\theta^{(1)}, \ldots, \theta^{(K)}\right)$ we can represent the target distribution as

$$
\begin{equation*}
\pi^{d}\left(x^{d}\right) \propto \prod_{k=1}^{K} \psi_{k}\left(\theta^{(k-1)}, \theta^{(k)}\right), \tag{42}
\end{equation*}
$$

where $d=\sum_{k=1}^{K} n_{k},\left\{\psi_{k}\right\}$ are the potentials, and without loss of generality we assumed $\theta^{(0)}$ to be the observed data.

In the following, we show that (A5) holds for the class of graphical models represented by Eq. (42) under certain conditions.

Proposition 4.4. For the class of graphical models represented by Eq. (42), if $\theta^{(k)}=$ $\left(\theta_{1}^{(k)}, \theta_{2}^{(k)}, \ldots, \theta_{n_{k}}^{(k)}\right)$ are independent conditional on $\theta^{(k-1)}$ and $\theta^{(k+1)}$ and this holds for all $k$. Moreover, if under $X^{d}=\left(\theta^{(1)}, \ldots, \theta^{(K)}\right) \sim \pi^{d}$ all the potentials $\psi_{k}$ satisfy

$$
\begin{equation*}
\sup _{i \in\left\{1, \ldots, n_{k}\right\}}\left|\frac{\partial \log \psi_{k}}{\partial \theta_{i}^{(k)}}\right|=\mathcal{O}_{\mathbb{P}}\left(\sqrt{d / n_{k}}\right), \quad \sup _{j \in\left\{1, \ldots, n_{k-1}\right\}}\left|\frac{\partial \log \psi_{k}}{\partial \theta_{j}^{(k-1)}}\right|=\mathcal{O}_{\mathbb{P}}\left(\sqrt{d / n_{k-1}}\right) \tag{43}
\end{equation*}
$$

then (A5) holds.

Next, we extend the simple Gaussian example in Example 4.1 to a more realistic MCMC model which belongs to both classes of graphical models in Eqs. (41) and (42) and show that all the assumptions for the optimal scaling result in Theorem 3.14 hold.

Example 4.5 (A Realistic MCMC Model). Consider a realistic MCMC model

$$
\begin{align*}
Y_{i j} \mid \theta_{i j} & \sim \mathcal{N}\left(\theta_{i j}, W\right), \quad i, j \in\{1, \ldots, n\} \\
\theta_{i j} \mid \mu_{j} & \sim \mathcal{N}\left(\mu_{j}, V\right), \quad i \in\{1, \ldots, n\} \\
\mu_{j} \mid v & \sim \mathcal{N}(v, A)  \tag{44}\\
v & \sim \text { flat prior on } \mathbb{R}, \\
A & \sim \mathbf{I G}(a, b),
\end{align*}
$$

where $x^{d}=\left(\nu, A,\left\{\mu_{j}\right\}_{j=1}^{n},\left\{\theta_{i j}\right\}_{i, j=1}^{n}\right)$ are parameters, $\left\{Y_{i j}\right\}$ are the observed data, and $a, b, W, V$ are known constants.

We further assume that the observed data $\left\{Y_{i j}\right\}$ is not abnormal so that the posterior of the hyperparameter $A$ concentrates to some unknown constant.

Assumption. The posterior of the hyperparameter $A$ in Example 4.5 concentrates to some unknown constant $A_{0}>0$ as $n \rightarrow \infty$.

Note that this is a very reasonable assumption which implies the MCMC model is not seriously misspecified. We do not discuss sufficient conditions on the observed data $\left\{Y_{i j}\right\}_{i, j=1}^{n}$ for concentration of posterior distribution of $A$ here since it is not the focus of this paper. Next, we show that, under this assumption, the realistic MCMC model satisfies all the conditions required for optimal scaling in Theorem 3.14. Therefore, the acceptance rate 0.234 is indeed asymptotically optimal for this MCMC model in the sense of maximizing ESJD.

Proposition 4.6. Under the above assumption, the optimal asymptotic acceptance rate for the realistic MCMC model in Example 4.5 is (to three decimal places) 0.234.

Proof. See Appendix E.

The authors thank Jeffrey Negrea for suggestions on graphical models, and Aaron Smith for helpful discussions. J. R. is partly supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada.

## Appendix A. Proof of Theorem 3.10

Throughout the proof, for simplicity, we assume the coordinates are linear ordered. The "neighborhoods" of a coordinate is defined by $\mathcal{H}_{i}:=\left\{j:|i-j|<l_{d}\right\}$. Therefore sup ${ }_{(i, j): j \in \mathcal{H}_{i}}$ can be simplified to $\sup _{|i-j|<l_{d}}$ and $\sup _{(i, j): j \notin \mathcal{H}_{i}}$ can be simplified to $\sup _{|i-j| \geq l_{d}}$. Note that the use of linear ordering is only for simplifying notations. It is straightforward to extend the proof to the cases of general ordering.

For Theorem 3.10, we only prove

$$
\begin{equation*}
\left|\operatorname{ESJD}(d)-2 \frac{d \ell^{2}}{d-1} \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right| \rightarrow 0 \tag{45}
\end{equation*}
$$

since the proof of

$$
\begin{equation*}
\left|\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y^{d}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)-2 \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right| \rightarrow 0 \tag{46}
\end{equation*}
$$

follows similarly.
First, we write $\operatorname{ESJD}$ as $\operatorname{ESJD}(d)=: \sum_{i=1}^{d} \operatorname{ESJD}_{i}(d)$, where

$$
\begin{equation*}
\operatorname{ESJD}_{i}(d):=\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y^{d}}\left[\left(Y_{i}-X_{i}\right)^{2}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)\right] \tag{47}
\end{equation*}
$$

Then it suffices to show that

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}}\left|\operatorname{ESJD}_{i}(d)-\frac{2 \ell^{2}}{d-1} \mathbb{E}_{X^{d} \sim \pi^{d}}\left[\Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right|=o\left(d^{-1}\right) . \tag{48}
\end{equation*}
$$

Writing $\operatorname{ESJD}_{i}(d)=\mathbb{E}_{X^{d} \sim \pi^{d}} \mathbb{E}_{Y_{i}}\left[\left(Y_{i}-X_{i}\right)^{2} \mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)\right]$, it suffices to show that uniformly over $i \in\{1, \ldots, d\}$

$$
\begin{align*}
& \mathbb{E}_{X^{d} \sim \pi^{d}}\left|\mathbb{E}_{Y_{i}}\left[\left(Y_{i}-X_{i}\right)^{2} \mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)\right]-\frac{2 \ell^{2}}{d-1} \Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right|  \tag{49}\\
& =\mathbb{E}_{X^{d} \sim \pi^{d}}\left|\mathbb{E}_{Y_{i}}\left\{\left(Y_{i}-X_{i}\right)^{2}\left[\mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(X^{d}\right)}\right)-2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(X^{d}\right)}}{2}\right)\right]\right\}\right|  \tag{50}\\
& =o\left(d^{-1}\right) . \tag{51}
\end{align*}
$$

It then suffices to show

$$
\begin{align*}
& \sup _{x^{d} \in F_{d}}\left|\mathbb{E}_{Y_{i}}\left\{\left(Y_{i}-x_{i}\right)^{2} \mathbb{1}_{y^{d}(i) \in F_{d}^{(i)}}\left[\mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right)-2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(x^{d}\right)}}{2}\right)\right]\right\}\right|  \tag{52}\\
& \leq \mathbb{E}_{Y_{i}}\left\{\left(Y_{i}-x_{i}\right)^{2} \sup _{y^{d}(i) \in F_{d}^{(i)}, x^{d} \in F_{d}}\left|\mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right)-2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(x^{d}\right)}}{2}\right)\right|\right\}=o\left(d^{-1}\right), \tag{53}
\end{align*}
$$

where $y^{d}(i):=\left(x_{1}, \ldots, x_{i-1}, Y_{i}, x_{i+1}, \ldots, x_{d}\right)$. Defining $M_{x^{d}}^{(i)}\left(Y_{i}\right):=\mathbb{E}_{Y_{-i}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right)$, since

$$
\begin{align*}
\log \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)} & =\log \frac{\pi_{i}\left(Y_{i}\right)}{\pi_{i}\left(x_{i}\right)}+\log \frac{\pi_{-i}\left(Y_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}  \tag{54}\\
& =\left(\log \frac{\pi_{i}\left(Y_{i}\right)}{\pi_{i}\left(x_{i}\right)}+\log \frac{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}\right)+\log \frac{\pi_{-i}\left(Y_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)} \tag{55}
\end{align*}
$$

we can write

$$
\begin{align*}
M_{x^{d}}^{(i)}\left(Y_{i}\right) & =\mathbb{E}_{Y_{-i}}\left[1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right]=\mathbb{E}_{Y_{-i}}\left[1 \wedge \exp \left(\log \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right)\right]  \tag{56}\\
& =\mathbb{E}_{Y_{-i}}\left[1 \wedge \exp \left(\log \frac{\pi_{i}\left(Y_{i}\right)}{\pi_{i}\left(x_{i}\right)}+\log \frac{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}+\log \frac{\pi_{-i}\left(Y_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}\right)\right] . \tag{57}
\end{align*}
$$

Note that the expectation is taken over $Y_{-i}$ and only the last term, $\log \frac{\pi_{-i}\left(Y_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}$, involves $Y_{-i}$.
In the following, we then first focus on approximating $\log \frac{\pi_{-i}\left(Y_{-i} \mid x_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}$ for given $x^{d} \in F_{d}^{+}$. Since $Y^{d} \sim \mathcal{N}\left(x^{d}, \frac{\ell^{2}}{d-1} I\right)$, we first approximate $\log \frac{\pi_{-i}\left(Y_{-i} \mid x_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}$ by the first two terms of its Taylor expansion.

Define

$$
\begin{equation*}
m_{1}^{(i)}\left(Y_{-i}, x^{d}\right):=\left(\nabla \log \pi_{-i}\right)^{T}\left(Y_{-i}-x_{-i}\right)+\frac{1}{2}\left(Y_{-i}-x_{-i}\right)^{T}\left[\nabla^{2} \log \pi_{-i}\right]\left(Y_{-i}-x_{-i}\right) \tag{58}
\end{equation*}
$$

where

$$
\begin{equation*}
\left(\nabla \log \pi_{-i}\right)^{T}\left(Y_{-i}-x_{-i}\right):=\sum_{j \in\{1, \ldots, d\}, j \neq i} \frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j}}\left(Y_{j}-x_{j}\right) \tag{59}
\end{equation*}
$$

and $\left[\nabla^{2} \log \pi_{-i}\right]$ denotes the $(d-1) \times(d-1)$ matrix with elements

$$
\left\{\frac{\partial^{2} \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j} \partial x_{k}}\right\}_{j, k \in\{1, \ldots, d\}, j \neq i, k \neq i}
$$

Then, we have the following result.
Lemma A.1. Uniformly over $i \in\{1, \ldots, d\}$, we have

$$
\begin{equation*}
\sup _{x^{d} \in F_{d}^{+}} \mathbb{E}_{Y_{-i}}\left[\left|m_{1}^{(i)}\left(Y_{-i}, x^{d}\right)-\log \frac{\pi_{-i}\left(Y_{-i} \mid x_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}\right|\right] \rightarrow 0 \tag{60}
\end{equation*}
$$

Proof. See Appendix B.1.
Next, we approximate the second order term of the Taylor approximation $\frac{1}{2}\left(Y_{-i}-x_{-i}\right)^{T}$ $\left[\nabla^{2} \log \pi_{-i}\right]\left(Y_{-i}-x_{-i}\right)$ by a non-random term $\frac{1}{2} \frac{\ell^{2}}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}}$.

Lemma A.2. Uniformly over $i \in\{1, \ldots, d\}$, we have

$$
\begin{equation*}
\sup _{x^{d} \in F_{d}^{+}} \mathbb{E}_{Y_{-i}}\left[\left|\left(Y_{-i}-x_{-i}\right)^{T}\left[\nabla^{2} \log \pi_{-i}\right]\left(Y_{-i}-x_{-i}\right)-\frac{\ell^{2}}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}}\right|\right] \rightarrow 0 . \tag{61}
\end{equation*}
$$

Proof. See Appendix B.2.

## Defining

$$
\begin{equation*}
m_{2}^{(i)}\left(Y_{-i}, x^{d}\right):=\left(\nabla \log \pi_{-i}\right)^{T}\left(Y_{-i}-x_{-i}\right)+\frac{1}{2} \frac{\ell^{2}}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}}, \tag{62}
\end{equation*}
$$

we have

$$
\begin{equation*}
m_{2}^{(i)}\left(Y_{-i}, x^{d}\right) \sim \mathcal{N}\left(\ell^{2} S_{d}^{(i)} / 2, \ell^{2} R_{d}^{(i)}\right) \tag{63}
\end{equation*}
$$

where

$$
\begin{equation*}
R_{d}^{(i)}:=\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j}}\right)^{2}, \quad S_{d}^{(i)}:=\frac{1}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j}^{2}} . \tag{64}
\end{equation*}
$$

Next, we show we can approximate $S_{d}^{(i)}$ by $-R_{d}^{(i)}$.
Lemma A.3. There exists a sequence of subsets of states $\left\{F_{d}^{\prime}\right\}$, such that $\pi^{d}\left(F_{d}^{\prime}\right) \rightarrow 1$ and

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}} \sup _{x^{d} \in F_{d}^{\prime}}\left|R_{d}^{(i)}+S_{d}^{(i)}\right| \rightarrow 0 \tag{65}
\end{equation*}
$$

Proof. See Appendix B.3.
Now defining

$$
\begin{equation*}
m_{3}^{(i)}\left(Y_{-i}, x^{d}\right):=\left(\nabla \log \pi_{-i}\right)^{T}\left(Y_{-i}-x_{-i}\right)+\frac{1}{2} \frac{\ell^{2}}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j}}\right)^{2}, \tag{66}
\end{equation*}
$$

we have

$$
\begin{equation*}
m_{3}^{(i)}\left(Y_{-i}, x^{d}\right) \sim \mathcal{N}\left(-\ell^{2} R_{d}^{(i)} / 2, \ell^{2} R_{d}^{(i)}\right) \tag{67}
\end{equation*}
$$

By triangle inequality, we can write

$$
\begin{align*}
\left|m_{3}^{(i)}\left(Y_{-i}, x^{d}\right)-\log \frac{\pi_{-i}\left(Y_{-i} \mid x_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}\right| & \leq\left|m_{1}^{(i)}\left(Y_{-i}, x^{d}\right)-\log \frac{\pi_{-i}\left(Y_{-i} \mid x_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}\right|  \tag{68}\\
& +\left|m_{2}^{(i)}\left(Y_{-i}, x^{d}\right)-m_{1}^{(i)}\left(Y_{-i}, x^{d}\right)\right|  \tag{69}\\
& +\left|m_{3}^{(i)}\left(Y_{-i}, x^{d}\right)-m_{2}^{(i)}\left(Y_{-i}, x^{d}\right)\right| . \tag{70}
\end{align*}
$$

Therefore, using Lemmas A.1-A.3, we get

Next, we abuse the notation a little bit by defining

$$
\begin{equation*}
R_{d}^{(i)}(y):=\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}=y\right)}{\partial x_{j}}\right)^{2} \tag{72}
\end{equation*}
$$

Then by the definition of $m_{3}^{(i)}$, we replace $x^{d}$ by $y^{d}(i)=\left(x_{1}, \ldots, x_{i-1}, Y_{i}, x_{i+1}, \ldots, x_{d}\right)$, which yields

$$
\begin{align*}
m_{3}^{(i)}\left(Y_{-i}, y^{d}(i)\right)= & \left(\nabla \log \pi_{-i}\left(x_{-i} \mid Y_{i}\right)\right)^{T}\left(Y_{-i}-x_{-i}\right)  \tag{73}\\
& +\frac{1}{2} \frac{\ell^{2}}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid Y_{i}\right)}{\partial x_{j}}\right)^{2} . \tag{74}
\end{align*}
$$

Then, we have

$$
\begin{equation*}
m_{3}^{(i)}\left(Y_{-i}, y^{d}(i)\right) \sim \mathcal{N}\left(-\ell^{2} R_{d}^{(i)}\left(Y_{i}\right) / 2, \ell^{2} R_{d}^{(i)}\left(Y_{i}\right)\right) . \tag{75}
\end{equation*}
$$

Recall that $M_{x^{d}}^{(i)}\left(Y_{i}\right)=\mathbb{E}_{Y_{-i}}\left[1 \wedge \exp \left(\log \frac{\pi_{i}\left(Y_{i}\right)}{\pi_{i}\left(x_{i}\right)}+\log \frac{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}+\log \frac{\pi_{-i}\left(Y_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}\right)\right]$, defining

$$
\begin{equation*}
\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)=\mathbb{E}_{Y_{-i}}\left[1 \wedge \exp \left(\log \frac{\pi_{i}\left(Y_{i}\right)}{\pi_{i}\left(x_{i}\right)}+\log \frac{\pi_{-i}\left(x_{-i} \mid Y_{i}\right)}{\pi_{-i}\left(x_{-i} \mid x_{i}\right)}+m_{3}^{(i)}\left(Y_{-i}, y^{d}(i)\right)\right)\right], \tag{76}
\end{equation*}
$$

we next apply the following two lemmas from [54].
Lemma A. 4 ([54, Proposition 2.2]). The function $g(x)=1 \wedge e^{x}$ is Lipschitz such that

$$
\begin{equation*}
|g(x)-g(y)| \leq|x-y|, \quad \forall x, y . \tag{77}
\end{equation*}
$$

Lemma A. 5 ([54, Proposition 2.4]). If $z \sim \mathcal{N}\left(\mu, \sigma^{2}\right)$ then

$$
\begin{equation*}
\mathbb{E}\left(1 \wedge e^{z}\right)=\Phi(\mu / \sigma)+\exp \left(\mu+\sigma^{2} / 2\right) \Phi(-\sigma-\mu / \sigma) \tag{78}
\end{equation*}
$$

By Lemma A. 4 and Eq. (71), we have that uniformly over $i \in\{1, \ldots, d\}$

$$
\begin{equation*}
\sup _{y^{d}(i) \in F_{d}^{+} \cap F_{d}^{\prime}}\left|M_{x^{d}}^{(i)}\left(Y_{i}\right)-\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)\right| \rightarrow 0 . \tag{79}
\end{equation*}
$$

Applying Lemma A. 5 to $\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)$ yields

$$
\begin{align*}
\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)= & \Phi\left(R_{d}^{(i)}\left(Y_{i}\right)^{-1 / 2}\left(\ell^{-1} \log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)}-\ell R_{d}^{(i)}\left(Y_{i}\right) / 2\right)\right)  \tag{80}\\
& +\exp \left(\log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)}\right) \Phi\left(-\ell R_{d}^{(i)}\left(Y_{i}\right)^{1 / 2} / 2-\log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)} R_{d}^{(i)}\left(Y_{i}\right)^{-1 / 2} \ell^{-1}\right) . \tag{81}
\end{align*}
$$

Note that it is easy to check that $\hat{M}_{x^{d}}^{(i)}\left(x_{i}\right)=2 \Phi\left(-\frac{\ell \sqrt{R_{d}^{(i)}}}{2}\right)$. We then show $\hat{M}_{x^{d}}^{(i)}\left(x_{i}\right)$ converges to $2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(x^{d}\right)}}{2}\right)$.

## Lemma A.6.

Proof. See Appendix B.4.

Finally, using Taylor expansion together with $\mathbb{E}_{Y_{i}}\left(Y_{i}-x_{i}\right)^{2}=\ell^{2} /(d-1)$ and $\mathbb{E}_{Y_{i}}\left|Y_{i}-x_{i}\right|^{3}=$ $\mathcal{O}\left(d^{-3 / 2}\right)$, we have

$$
\begin{align*}
& \mathbb{E}_{Y_{i}}\left\{\left(Y_{i}-x_{i}\right)^{2} \sup _{y^{d}(i) \in F_{d}^{+}}\left|\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)-2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(x^{d}\right)}}{2}\right)\right|\right\}  \tag{83}\\
& \leq \frac{\ell^{2}}{d-1} \sup _{x^{d} \in F_{d}^{+}}\left|2 \Phi\left(-\frac{\ell \sqrt{R_{d}^{(i)}}}{2}\right)-2 \Phi\left(-\frac{\ell \sqrt{I_{d}\left(x^{d}\right)}}{2}\right)\right|  \tag{84}\\
& \quad+\mathcal{O}\left(d^{-3 / 2}\right) \sup _{y^{d}(i) \in F_{d}^{+}}\left|\frac{\mathrm{d} \hat{M}_{x^{d}}^{(i)}\left(y_{i}\right)}{\mathrm{d} y_{i}}\left(Y_{i}\right)\right| . \tag{85}
\end{align*}
$$

For the last term, we have the following lemma.

## Lemma A.7.

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}} \sup _{y^{d}(i) \in F_{d}^{+}}\left|\frac{\mathrm{d} \hat{M}_{x^{d}}^{(i)}\left(y_{i}\right)}{\mathrm{d} y_{i}}\left(Y_{i}\right)\right|=o\left(d^{1 / 2}\right) . \tag{86}
\end{equation*}
$$

## Proof. See Appendix B.5.

The proof of Theorem 3.10 is completed by applying Lemmas A. 6 and A. 7.

## Appendix B. Proof of Lemmas in Appendix A

## B.1. Proof of Lemma A. 1

For $x^{d} \in F_{d}^{+}$, by Taylor expansion and mean value theorem, we have

$$
\begin{align*}
& \left|\log \pi_{-i}\left(Y_{-i} \mid x_{i}\right)-\log \pi_{-i}\left(x_{-i} \mid x_{i}\right)-m_{1}\left(Y_{-i}, x^{d}\right)\right|  \tag{87}\\
& \leq \sup _{\tilde{x}^{d} \in \mathbb{R}^{d}}\left|\frac{1}{6} \sum_{j, k, l \neq i} \frac{\partial^{3} \log \pi^{d}\left(\tilde{x}^{d}\right)}{\partial x_{j} \partial x_{k} \partial x_{l}}\left(Y_{j}-x_{j}\right)\left(Y_{k}-x_{k}\right)\left(Y_{l}-x_{l}\right)\right| . \tag{88}
\end{align*}
$$

In the above summation, the summation over the cases of $j=k=l$ equals

$$
\begin{equation*}
\sup _{\tilde{x}^{d} \in \mathbb{R}^{d}}\left|\frac{\partial^{3} \log \pi^{d}\left(\tilde{x}^{d}\right)}{\partial x_{j}^{3}}\right| \mathcal{O}\left(d \mathbb{E}\left|Y_{j}-x_{j}\right|^{3}\right)=o\left(d^{1 / 2}\right) \mathcal{O}\left(d\left(\sqrt{\ell^{2} /(d-1)}\right)^{3}\right)=o(1) \tag{89}
\end{equation*}
$$

For the cases of $j=k \neq l$, we have

$$
\begin{equation*}
\sum_{j=k \neq l} \frac{\partial^{3} \log \pi_{-i}\left(\tilde{x}^{d}\right)}{\partial x_{j}^{2} \partial x_{l}}\left(Y_{j}-x_{j}\right)^{2}\left(Y_{l}-x_{l}\right)=\sum_{j}\left(Y_{j}-x_{j}\right)^{2} \sum_{l \neq k} \frac{\partial^{3} \log \pi_{-i}\left(\tilde{x}^{d}\right)}{\partial x_{j}^{2} \partial x_{l}}\left(Y_{l}-x_{l}\right) \tag{90}
\end{equation*}
$$

By Assumption (A3), we have $\mathbb{E}\left|\sum_{j \neq l} \frac{\partial^{3} \log \pi_{-i}\left(\tilde{x}^{d}\right)}{\partial x_{j}^{2} \partial x_{l}}\left(Y_{l}-x_{l}\right)\right|=\mathcal{O}\left(l_{d} / d\right) o\left(d / l_{d}\right)=o(1)$ since $\frac{\partial^{3} \log \pi^{d}\left(\tilde{x}^{d}\right)}{\partial x_{j}^{\partial} \partial x_{l}}$ goes to zero when $|k-i|>l_{d}$. Then, by $\mathbb{E}\left|Y_{j}-x_{j}\right|^{2}=\mathcal{O}(1 / d)$, the summation over all cases of $j=k \neq l$ equals $d \mathcal{O}_{\mathbb{P}}(1 / d) o_{\mathbb{P}}(1)=o_{\mathbb{P}}(1)$.

Finally, for $j \neq k \neq l$, it suffices to show

$$
\begin{align*}
& \sup _{\tilde{x}^{d} \in \mathbb{R}^{d}}\left|\sum_{j \neq k \neq l \neq i} \frac{\partial^{3} \log \pi_{-i}\left(\tilde{x}^{d}\right)}{\partial x_{j} \partial x_{k} \partial x_{l}}\left(Y_{j}-x_{j}\right)\left(Y_{k}-x_{k}\right)\left(Y_{l}-x_{l}\right)\right|  \tag{91}\\
& \leq \sum_{i \neq j \neq k \neq l}\left(\sup _{\tilde{x}^{d} \in \mathbb{R}^{d}}\left|\frac{\partial^{3} \log \pi_{-i}\left(\tilde{x}^{d}\right)}{\partial x_{j} \partial x_{k} \partial x_{l}}\right|\right)\left|\left(Y_{j}-x_{j}\right)\left(Y_{k}-x_{k}\right)\left(Y_{l}-x_{l}\right)\right|=o_{\mathbb{P}}(1) . \tag{92}
\end{align*}
$$

Note that $\left\{\left|\left(Y_{j}-x_{j}\right)\left(Y_{k}-x_{k}\right)\left(Y_{l}-x_{l}\right)\right|\right\}_{j \neq k \neq l}$ are independent random variables which do not depend on the values of $x_{j}, x_{k}, x_{l}$, and

$$
\begin{equation*}
\left|\left(Y_{j}-x_{j}\right)\left(Y_{k}-x_{k}\right)\left(Y_{l}-x_{l}\right)\right|=\mathcal{O}_{\mathbb{P}}\left(\left(\sqrt{\ell^{2} /(d-1)}\right)^{3}\right)=\mathcal{O}_{\mathbb{P}}\left(d^{-3 / 2}\right) \tag{93}
\end{equation*}
$$

Therefore, the summation for cases $j \neq k \neq l$ is $o_{\mathbb{P}}(1)$ under Assumption (A3). We have proven the result for fixed $i$. Finally, it is easy to check the proof holds uniformly over $i \in\{1, \ldots, d\}$.

## B.2. Proof of Lemma A. 2

Lemma B. 1 (Quadratic Form of Gaussian Random Vector). If $z^{d} \sim \mathcal{N}_{d}(\mu, \Sigma)$, then

$$
\begin{equation*}
\mathbb{E}\left(z^{T} A z\right)=\operatorname{tr}(A \Sigma)+\mu^{T} A \mu, \quad \operatorname{var}\left(z^{T} A z\right)=2 \operatorname{tr}(A \Sigma A \Sigma)+4 \mu^{T} A \Sigma A \mu \tag{94}
\end{equation*}
$$

Note that $Y_{-i} \sim \mathcal{N}_{d-1}\left(x_{-i}, \frac{\ell^{2}}{d-1} I\right)$ and $\left(Y_{-i}-x_{-i}\right)^{T}\left[\nabla^{2} \log \pi_{-i}\right]\left(Y_{-i}-x_{-i}\right)$ is a quadratic form of Gaussian random vector. By Lemma B.1,

$$
\begin{equation*}
\mathbb{E}\left[\left(Y_{-i}-x_{-i}\right)^{T}\left[\nabla^{2} \log \pi_{-i}\right]\left(Y_{-i}-x_{-i}\right)\right]=\frac{\ell^{2}}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}} . \tag{95}
\end{equation*}
$$

Therefore, it suffices to show the variance of the quadratic form goes to zero. Using the assumptions, the variance satisfies

$$
\begin{align*}
& \frac{2 \ell^{4}}{(d-1)^{2}} \operatorname{tr}\left(\left[\nabla^{2} \log \pi_{-i}\right]\left[\nabla^{2} \log \pi_{-i}\right]\right)  \tag{96}\\
& =\frac{2 \ell^{4}}{(d-1)^{2}} \sum_{j \neq i} \sum_{k \neq i}\left(\frac{\partial^{2} \log \pi_{-i}}{\partial x_{j} \partial x_{k}}\right)^{2}  \tag{97}\\
& \leq \frac{2 \ell^{4}}{(d-1)^{2}} \sum_{l=0}^{d-1} \sum_{\{j, k:|j-k|=l\}}\left(\frac{\partial^{2} \log \pi^{d}}{\partial x_{j} \partial x_{k}}\right)^{2}  \tag{98}\\
& =\frac{2 \ell^{4}}{(d-1)^{2}} \sum_{l \leq l_{d}} \sum_{\{j, k:|j-k|=l\}}\left(\frac{\partial^{2} \log \pi^{d}}{\partial x_{i} \partial x_{j}}\right)^{2}  \tag{99}\\
& \quad+\frac{2 \ell^{4}}{(d-1)^{2}} \sum_{l>l_{d}} \sum_{\{j, k:|j-k|=l\}}\left(\frac{\partial^{2} \log \pi^{d}}{\partial x_{j} \partial x_{k}}\right)^{2}  \tag{100}\\
& \leq \frac{2 \ell^{4}}{(d-1)^{2}}(d-1) l_{d} \sup _{|j-k| \leq l_{d}} \sup _{x^{d} \in F_{d}^{+}}\left(\frac{\partial^{2} \log \pi^{d}}{\partial x_{j} \partial x_{k}}\right)^{2} \tag{101}
\end{align*}
$$

$$
\begin{align*}
& \quad+\frac{2 \ell^{4}}{(d-1)^{2}}(d-1)^{2} \sup _{|j-k|>l_{d}} \sup _{x^{d} \in F_{d}^{+}}\left(\frac{\partial^{2} \log \pi^{d}}{\partial x_{j} \partial x_{k}}\right)^{2}  \tag{102}\\
& =\mathcal{O}\left(l_{d} / d\right) o\left(d / l_{d}\right)+o(1)=o(1) \tag{103}
\end{align*}
$$

where we have used $\sup _{x^{d} \in F_{d}^{+}} \sup _{|j-k| \leq l_{d}} \frac{\partial^{2} \log \pi^{d}}{\partial x_{j} \partial x_{k}}=o\left(\sqrt{d / l_{d}}\right)$ from Assumption (A1).

## B.3. Proof of Lemma A. 3

Note that

$$
\begin{align*}
R_{d}^{(i)}+S_{d}^{(i)} & =\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}}{\partial x_{j}}\right)^{2}+\frac{1}{d-1} \sum_{j \neq i} \frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}}  \tag{104}\\
& =\frac{1}{d-1} \sum_{j \neq i}\left\{\left(\frac{\partial \log \pi^{d}}{\partial x_{j}}\right)^{2}+\frac{\partial^{2} \log \pi^{d}}{\partial x_{j}^{2}}\right\}  \tag{105}\\
& =\frac{1}{d-1} \sum_{j \neq i}\left\{\frac{1}{\left(\pi^{d}\right)^{2}}\left(\frac{\partial \pi^{d}}{\partial x_{j}}\right)^{2}+\frac{\partial}{\partial x_{j}}\left(\frac{\partial \log \pi^{d}}{\partial x_{j}}\right)\right\}  \tag{106}\\
& =\frac{1}{d-1} \sum_{j \neq i}\left\{\frac{1}{\left(\pi^{d}\right)^{2}}\left(\frac{\partial \pi^{d}}{\partial x_{j}}\right)^{2}+\frac{\partial}{\partial x_{j}}\left(\frac{1}{\pi^{d}} \frac{\partial \pi^{d}}{\partial x_{j}}\right)\right\}  \tag{107}\\
& =\frac{1}{d-1} \sum_{j \neq i}\left\{\frac{1}{\left(\pi^{d}\right)^{2}}\left(\frac{\partial \pi^{d}}{\partial x_{j}}\right)^{2}+\frac{\pi^{d} \frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}}-\left(\frac{\partial \pi^{d}}{\partial x_{j}}\right)^{2}}{\left(\pi^{d}\right)^{2}}\right\}  \tag{108}\\
& =\frac{1}{(d-1)} \sum_{j \neq i} \frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}} . \tag{109}
\end{align*}
$$

Next, we show $\mathbb{E}\left[\sup _{i}\left(R_{d}^{(i)}+S_{d}^{(i)}\right)^{2}\right]$ converges to 0 . To prove this, consider writing $\mathbb{E}\left[\sup _{i}\left(R_{d}^{(i)}+S_{d}^{(i)}\right)^{2}\right]$ as sum of $(d-1)^{2}$ terms

$$
\begin{align*}
\mathbb{E} & {\left[\sup _{i}\left(R_{d}^{(i)}+S_{d}^{(i)}\right)^{2}\right]=\frac{1}{(d-1)^{2}} \int \sup _{i} \sum_{j \neq i} \sum_{k \neq i}\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d} }  \tag{110}\\
\leq & \frac{1}{(d-1)^{2}} \sum_{j=1}^{d} \sum_{k=1}^{d} \int\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d} \\
& -\frac{2}{(d-1)^{2}} \int \inf _{i} \sum_{j \neq i}\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d}  \tag{111}\\
= & \frac{1}{(d-1)^{2}} \sum_{j=1}^{d} \sum_{k=1}^{d} \int\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d}+o(1), \tag{112}
\end{align*}
$$

where the last equality follows from

$$
\begin{align*}
\frac{2}{(d-1)^{2}} \int \inf _{i} \sum_{j \neq i}\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d} & \geq \frac{2}{(d-1)^{2}} \int \inf _{i} \sum_{j \neq i}\left(\frac{\partial^{2} \log \pi_{-i}}{\partial x_{j}^{2}}\right) \pi^{d} \mathrm{~d} x^{d}  \tag{113}\\
& =\frac{2}{(d-1)^{2}} o\left(d \sqrt{d / l_{d}}\right)=o(1) \tag{114}
\end{align*}
$$

When $|j-k| \geq l_{d}$, by Assumption (A2), we have

$$
\begin{align*}
& \int\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}} \frac{1}{\pi^{d}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}} \frac{1}{\pi^{d}}\right) \pi^{d} \mathrm{~d} x^{d}  \tag{115}\\
& =\int\left(\frac{\partial^{2} \pi^{d}}{\partial x_{j}^{2}}\right)\left(\frac{\partial^{2} \pi^{d}}{\partial x_{k}^{2}}\right) \frac{1}{\pi^{d}} \mathrm{~d} x^{d}  \tag{116}\\
& =\int\left(\frac{\partial^{2} \pi_{j, k \mid-j-k}}{\partial x_{j}^{2}}\right)\left(\frac{\partial^{2} \pi_{j, k \mid-j-k}}{\partial x_{k}^{2}}\right) \frac{1}{\pi_{j, k \mid-j-k}} \pi_{-j-k} \mathrm{~d} x_{-j-k} \mathrm{~d} x_{j} \mathrm{~d} x_{k}  \tag{117}\\
& \leq \int\left[\sup _{x^{d} \in F_{d}} \int\left(\frac{\partial^{2} \pi_{j, k \mid-j-k}}{\partial x_{j}^{2}}\right)\left(\frac{\partial^{2} \pi_{j, k \mid-j-k}}{\partial x_{k}^{2}}\right) \frac{1}{\pi_{j, k \mid-j-k}} \mathrm{~d} x_{j} \mathrm{~d} x_{k}\right] \pi_{-j-k} \mathrm{~d} x_{-j-k}  \tag{118}\\
& \rightarrow 0 . \tag{119}
\end{align*}
$$

This implies $\mathbb{E}\left[\sup _{i}\left(R_{d}^{(i)}+S_{d}^{(i)}\right)^{2}\right]=\frac{\mathcal{O}\left(d l_{d}\right)+\left(d-l_{d}\right)^{2} o(1)}{(d-1)^{2}}+o(1) \rightarrow 0$. Therefore, uniformly over $i, R_{d}^{(i)}+S_{d}^{(i)} \rightarrow 0$ in probability, then there exists a sequence $\left\{F_{d}^{\prime}\right\}$ such that $\mathbb{P}\left(R_{d}^{(i)}+S_{d}^{(i)} \in\right.$ $\left.F_{d}^{\prime}, \forall i\right) \rightarrow 1$ and the following holds

$$
\begin{equation*}
\sup _{i} \sup _{x^{d} \in F_{d}^{\prime}}\left|R_{d}^{(i)}+S_{d}^{(i)}\right| \rightarrow 0 \tag{120}
\end{equation*}
$$

## B.4. Proof of Lemma A. 6

Note that Assumption (A4) implies

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}_{x^{d} \in F_{d}^{+}}} \sup _{\partial x_{i}} \frac{\partial}{\partial x^{d}} \log \pi^{d}\left(x^{d}\right)=o\left(d^{1 / 2}\right) . \tag{121}
\end{equation*}
$$

Then, by the definitions of $R_{d}^{(i)}$ and $I_{d}\left(x^{d}\right)$, we have

$$
\begin{align*}
R_{d}^{(i)}-I_{d}\left(x^{d}\right) & =\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}\right)}{\partial x_{j}}\right)^{2}-\frac{1}{d} \sum_{j=1}^{d}\left(\frac{\partial}{\partial x_{j}} \log \pi^{d}\left(x^{d}\right)\right)^{2}  \tag{122}\\
& =\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{j}}\right)^{2}-\frac{1}{d} \sum_{j=1}^{d}\left(\frac{\partial}{\partial x_{j}} \log \pi^{d}\left(x^{d}\right)\right)^{2}  \tag{123}\\
& =\frac{1}{d} R_{d}^{(i)}-\frac{1}{d}\left(\frac{\partial}{\partial x_{i}} \log \pi^{d}\left(x^{d}\right)\right)^{2} \rightarrow 0 . \tag{124}
\end{align*}
$$

## B.5. Proof of Lemma A. 7

Recall that we have shown

$$
\begin{align*}
\hat{M}_{x^{d}}^{(i)}\left(Y_{i}\right)= & \Phi\left(R_{d}^{(i)}\left(Y_{i}\right)^{-1 / 2}\left(\ell^{-1} \log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)}-\ell R_{d}^{(i)}\left(Y_{i}\right) / 2\right)\right)  \tag{125}\\
& +\exp \left(\log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)}\right) \Phi\left(-\ell R_{d}^{(i)}\left(Y_{i}\right)^{1 / 2} / 2-\log \frac{\pi^{d}\left(y^{d}(i)\right)}{\pi^{d}\left(x^{d}\right)} R_{d}^{(i)}\left(Y_{i}\right)^{-1 / 2} \ell^{-1}\right) . \tag{126}
\end{align*}
$$

For notational simplicity, we omit the index $i$ and write $R_{d}^{(i)}$ by $R_{d}$. To simplify the derivation, we note that $\hat{M}_{x^{d}}^{(i)}(y)$ has the following form

$$
\begin{equation*}
M(y)=\Phi\left(f(y) g(y)-\frac{1}{2} f^{-1}(y)\right)+\exp (g(y)) \Phi\left(-\frac{1}{2} f^{-1}(y)-f(y) g(y)\right), \tag{127}
\end{equation*}
$$

where $f^{-1}(y):=\ell R_{d}^{1 / 2}(y)$ and $g(y)=\log \pi^{d}\left(y^{d}(i)\right)-\log \pi^{d}\left(x^{d}\right)$. Taking the derivative with respect to $y$, we get

$$
\begin{align*}
\frac{\mathrm{d} M(y)}{\mathrm{d} y}= & \Phi^{\prime}\left(f g-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)  \tag{128}\\
& +\exp (g) \Phi^{\prime}\left(-f^{-1} / 2-f g\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)  \tag{129}\\
& +\exp (g)\left(\frac{\mathrm{d}}{\mathrm{~d} y} g\right) \Phi\left(-f g-f^{-1} / 2\right)  \tag{130}\\
\leq & \left\|\Phi^{\prime}\right\|_{\infty}\left|\frac{\mathrm{d} f}{\mathrm{~d} y} g+\frac{\mathrm{d} g}{\mathrm{~d} y} f-\frac{1}{2} \frac{\mathrm{~d} f^{-1}}{\mathrm{~d} y}\right|  \tag{131}\\
& +\exp (g)\left\|\Phi^{\prime}\right\|_{\infty}\left|\frac{\mathrm{d} f}{\mathrm{~d} y} g+\frac{\mathrm{d} g}{\mathrm{~d} y} f+\frac{1}{2} \frac{\mathrm{~d} f^{-1}}{\mathrm{~d} y}\right|  \tag{132}\\
& +\exp (g)\left|\frac{\mathrm{d} g}{\mathrm{~d} y}\right|\|\Phi\|_{\infty} \tag{133}
\end{align*}
$$

Note that both $\Phi$ and $\Phi^{\prime}$ are bounded functions. It then suffices to show

$$
\begin{align*}
& \exp (g)\left|\frac{\mathrm{d} g}{\mathrm{~d} y}\right|=o\left(d^{1 / 2}\right), \quad \exp (g)\left|\frac{\mathrm{d} f}{\mathrm{~d} y} g\right|=o\left(d^{1 / 2}\right)  \tag{134}\\
& \exp (g)\left|\frac{\mathrm{d} g}{\mathrm{~d} y} f\right|=o\left(d^{1 / 2}\right), \quad \exp (g)\left|\frac{\mathrm{d} f^{-1}}{\mathrm{~d} y}\right|=o\left(d^{1 / 2}\right) \tag{135}
\end{align*}
$$

Observing that $\frac{\mathrm{d} f^{-1}}{\mathrm{~d} y}=\frac{1}{2} \ell R_{d}^{\prime} / R_{d}^{1 / 2}$ and $\frac{\mathrm{d} f}{\mathrm{~d} y}=-\frac{1}{2 \ell} \frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}$, if we can show

$$
\begin{equation*}
\sup _{i \in\{1, \ldots, d\}} \frac{\mathrm{d} R_{d}^{(i)}(y)}{\mathrm{d} y} \frac{1}{\left[R_{d}^{(i)}(y)\right]^{1 / 2}}=o(1) \tag{136}
\end{equation*}
$$

then we can get $\frac{\mathrm{d} f^{-1}}{\mathrm{~d} y}=o(1)$ and $\frac{\mathrm{d} f}{\mathrm{~d} y}=o\left(1 / R_{d}\right)$. Using $R_{d}^{(i)} \rightarrow I_{d}\left(x^{d}\right)$ from Appendix B.4, it suffices to show

$$
\begin{equation*}
\left(\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)\right)\left(\sup _{i} \sup _{x^{d} \in F_{d}^{(i)}} \frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}}\right)=o\left(d^{1 / 2}\right) \tag{137}
\end{equation*}
$$

$$
\begin{align*}
& \left(\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)\right)\left(\sup _{x^{d} \in F_{d}^{+}}\left|\log \left(\pi^{d}\left(x^{d}\right)\right) / I_{d}\left(x^{d}\right)\right|\right)=o\left(d^{1 / 2}\right),  \tag{138}\\
& \left(\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right)\right)\left(\sup _{i} \sup _{x^{d} \in F_{d}^{(i)}}\left|\frac{\partial \log \pi^{d}\left(x^{d}\right)}{\partial x_{i}} / \sqrt{I_{d}\left(x^{d}\right)}\right|\right)=o\left(d^{1 / 2}\right) . \tag{139}
\end{align*}
$$

One can easily verify that the above equations hold under Assumption (A4).
Finally, we complete the proof by showing Eq. (136). Recall that

$$
\begin{equation*}
R_{d}^{(i)}(y)=\frac{1}{d-1} \sum_{j \neq i}\left(\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}=y\right)}{\partial x_{j}}\right)^{2} \tag{140}
\end{equation*}
$$

For notational simplicity, we write

$$
\begin{equation*}
R_{d}^{(i)}(y)=\frac{1}{d-1} \sum_{j \neq i} f_{j}^{2}(y) \tag{141}
\end{equation*}
$$

where $f_{j}(y):=\frac{\partial \log \pi_{-i}\left(x_{-i} \mid x_{i}=y\right)}{\partial x_{j}}$. Then, by Cauchy-Schwarz inequality

$$
\begin{equation*}
\frac{\partial R_{d}^{(i)}(y)}{\mathrm{d} y}=\frac{2}{d-1} \sum_{j \neq i} f_{j}(y) f_{j}^{\prime}(y) \leq \frac{2}{d-1} \sqrt{\sum_{j \neq i} f_{j}^{2}(y) \sum_{j \neq i}\left|f_{j}^{\prime}(y)\right|^{2}} \tag{142}
\end{equation*}
$$

Note that by (A1), if $|i-j|>l_{d}$ then $f_{j}^{\prime}(y) \leq \sup _{x^{d} \in F_{d}} \frac{\partial^{2} \log \pi^{d}\left(x^{d}\right)}{\partial x_{i} \partial x_{j}} \rightarrow 0$. Hence, we have

$$
\begin{align*}
& \sup _{i \in\{1, \ldots, d\}} \frac{\mathrm{d} R_{d}^{(i)}(y)}{\mathrm{d} y} \frac{1}{\left[R_{d}^{(i)}(y)\right]^{1 / 2}} \leq \sup _{i} \frac{\frac{2}{d-1} \sqrt{\sum_{j \neq i} f_{j}^{2}(y) \sum_{j \neq i}\left|f_{j}^{\prime}(y)\right|^{2}}}{\sqrt{\frac{1}{d-1} \sum_{j \neq i} f_{j}^{2}(y)}}  \tag{143}\\
& =2 \sup _{i} \sqrt{\frac{1}{d-1} \sum_{j \neq i}\left|f_{j}^{\prime}(y)\right|^{2}} \leq 2 \sqrt{\frac{1}{d-1} \sum_{j=1}^{d}\left|f_{j}^{\prime}(y)\right|^{2}}=o\left(\sqrt{\frac{l_{d}}{d}\left(\sqrt{d / l_{d}}\right)^{2}}\right)=o(1) . \tag{144}
\end{align*}
$$

## Appendix C. Proof of Theorem 3.19

Similar to Appendix A, we assume the coordinates are linear ordered for simplicity. The proof follows the framework of Roberts et al. [54] using the generator approach [25].

Define the (discrete time) generator of $x^{d}$ by

$$
\begin{equation*}
\left(G_{d} f\right)\left(x^{d}\right):=d \mathbb{E}_{Y^{d}}\left\{\left[f\left(Y^{d}\right)-f\left(x^{d}\right)\right]\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right)\right\} \tag{145}
\end{equation*}
$$

for any function $f$ for which this definition makes sense. In the Skorokhod topology, it does not cause any problem to treat $G_{d}$ as a continuous time generator. We shall restrict attention to test functions such that $f\left(x^{d}\right)=f\left(x_{1}\right)$. We show uniform convergence of $G_{d}$ to $G$, the generator of the limiting (one-dimensional) Langevin diffusion, for a suitable large class of real-valued functions $f$, where, for some fixed function $h(\ell)$,

$$
\begin{equation*}
(G f)\left(x_{1}\right):=h(\ell)\left\{\frac{1}{2} f^{\prime \prime}\left(x_{1}\right)+\frac{1}{2}\left[(\log \tilde{\pi})^{\prime}\left(x_{1}\right)\right] f^{\prime}\left(x_{1}\right)\right\} \tag{146}
\end{equation*}
$$

in which $\tilde{\pi}$ is a one-dimensional density of the first coordinate of $\pi^{d}$. Since we have assumed in (A6) that $(\log \tilde{\pi})^{\prime}$ is Lipschitz, by Ethier and Kurtz [25, Thm 2.1 in Ch.8], a core for the generator has domain $C_{c}^{\infty}$, which is the class of continuous functions with compact support such that all orders of derivatives exist. This enables us to restrict attentions to functions $f_{c} \in C_{c}^{\infty}$ such that $f_{c}\left(x^{d}\right)=f_{c}\left(x_{1}\right)$.

Note that using Assumption (A2+), and the assumption $\pi^{d}\left(F_{d}^{c}\right)=\mathcal{O}\left(d^{-1-\delta}\right)$, following the arguments in the proof of Lemma A. 3 we can get a stronger version of Lemma A. 3 for $F_{d}^{\prime}:=\left\{x^{d}: \sup _{i}\left|R_{d}^{(i)}+S_{d}^{(i)}\right| \leq d^{-\delta}\right\}$. Then using a union bound yields

$$
\begin{equation*}
\mathbb{P}\left(X^{d}(\lfloor d s\rfloor) \notin F_{d} \cap F_{d}^{\prime}, \exists 0 \leq s \leq t\right) \rightarrow 0 . \tag{147}
\end{equation*}
$$

Therefore, for any fixed $t$, if $d \rightarrow \infty$ then the probability of all $X^{d}(\lfloor d s\rfloor), 0 \leq s \leq t$ are in $F_{d} \cap F_{d}^{\prime}$ goes to 1 . Since $F_{d} \cap F_{d}^{\prime} \subseteq F_{d}^{+} \cap F_{d}^{\prime} \subseteq F_{d}^{+}$, it suffices to consider $x^{d} \in F_{d}^{+}$.

Note that $Y^{d} \sim \mathcal{N}\left(x^{d}, \frac{\ell^{2}}{d-1} I\right)$, we can write

$$
\begin{equation*}
\left(G_{d} f_{c}\right)\left(x^{d}\right)=d \mathbb{E}_{Y_{1}}\left\{\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \mathbb{E}_{Y_{-1}}\left[1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right]\right\} \tag{148}
\end{equation*}
$$

where $\mathbb{E}_{Y_{-1}}[\cdot]$ is short for $\mathbb{E}_{Y_{2}, \ldots, Y_{d} \mid Y_{1}}[\cdot]$ and $\pi^{d}$ denotes the target distribution in $d$-dimension. The goal is then to prove $\left(G_{d} f_{c}\right)$ converges to $\left(G f_{c}\right)$.

Recall the definition Eq. (56), we omit the index to write $M_{x^{d}}^{(1)}$ as $M_{x^{d}}$, which is defined by

$$
\begin{equation*}
M_{x^{d}}\left(Y_{1}\right)=\mathbb{E}_{Y_{-1}}\left(1 \wedge \frac{\pi^{d}\left(Y^{d}\right)}{\pi^{d}\left(x^{d}\right)}\right) \tag{149}
\end{equation*}
$$

Then we have previously shown in Eq. (79) that $M_{x^{d}}\left(Y_{1}\right)$ can be approximated by

$$
\begin{align*}
\hat{M}_{x^{d}}\left(Y_{1}\right)= & \Phi\left(R_{d}\left(Y_{1}\right)^{-1 / 2}\left(\ell^{-1} \log \frac{\pi^{d}\left(Y_{1}, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)}-\ell R_{d}\left(Y_{1}\right) / 2\right)\right)  \tag{150}\\
& +\exp \left(\log \frac{\pi^{d}\left(Y_{1}, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)}\right) \Phi\left(-\ell R_{d}\left(Y_{1}\right)^{1 / 2} / 2-\log \frac{\pi^{d}\left(Y_{1}, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)} R_{d}\left(Y_{1}\right)^{-1 / 2} \ell^{-1}\right) \tag{151}
\end{align*}
$$

For $x^{d} \in F_{d}^{+}$, some properties of $\hat{M}_{x^{d}}$ are given as follows.
Lemma C.1. For $\hat{M}_{x^{d}}$, we have

$$
\begin{align*}
& \hat{M}_{x^{d}}\left(x_{1}\right)=2 \Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right)  \tag{152}\\
& \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)=\Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right) \frac{\mathrm{d}\left[\log \pi_{1}(x)+\log \pi_{-1}\left(x_{-1} \mid x\right)\right]}{\mathrm{d} x}\left(x_{1}\right)+o(1),  \tag{153}\\
& \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)=o\left(d^{1 / 2}\right), \quad \sup _{x^{d} \in F_{d}^{+}} \hat{M}_{x^{d}}^{\prime \prime}=o\left(d^{1 / 2}\right) . \tag{154}
\end{align*}
$$

Proof. See Appendix C.1.
Since $f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)$ is bounded, it suffices to show

$$
\begin{equation*}
\mathbb{E}_{Y_{1}}\left\{d\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \hat{M}_{x^{d}}\left(Y_{1}\right)\right\} \rightarrow\left(G f_{c}\right)\left(x_{1}\right) \tag{155}
\end{equation*}
$$

Now using mean value theorem and Taylor expansion of $\mathbb{E}_{Y_{1}}\left\{\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \hat{M}_{x^{d}}\left(Y_{1}\right)\right\}$ at ( $Y_{1}-x_{1}$ ) yields

$$
\begin{align*}
& {\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \hat{M}_{x^{d}}\left(Y_{1}\right)}  \tag{156}\\
& =\left[f_{c}^{\prime}\left(x_{1}\right)\left(Y_{1}-x_{1}\right)+\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right)\left(Y_{1}-x_{1}\right)^{2}+K\left(Y_{1}-x_{1}\right)^{3}\right]  \tag{157}\\
& \quad \cdot\left[\hat{M}_{x^{d}}\left(x_{1}\right)+\hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)\left(Y_{1}-x_{1}\right)+\frac{1}{2} \hat{M}_{x^{d}}^{\prime \prime}\left(x^{\prime}\right)\left(Y_{1}-x_{1}\right)^{2}\right]  \tag{158}\\
& =f_{c}^{\prime}\left(x_{1}\right) \hat{M}_{x^{d}}\left(x_{1}\right)\left(Y_{1}-x_{1}\right)+\left[\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right) \hat{M}_{x^{d}}\left(x_{1}\right)+f_{c}^{\prime}\left(x_{1}\right) \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)\right]\left(Y_{1}-x_{1}\right)^{2}  \tag{159}\\
& \quad+\left[K \hat{M}_{x^{d}}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right) \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)+\frac{1}{2} \hat{M}_{x^{d}}^{\prime \prime}\left(x^{\prime}\right) f_{c}^{\prime}\left(x_{1}\right)\right]\left(Y_{1}-x_{1}\right)^{3}  \tag{160}\\
& \quad+\left[\frac{1}{4} \hat{M}_{x^{d}}^{\prime \prime}\left(x^{\prime}\right) f_{c}^{\prime \prime}\left(x_{1}\right)+K \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)\right]\left(Y_{1}-x_{1}\right)^{4}+\frac{1}{2} \hat{M}_{x^{d}}^{\prime \prime}\left(x^{\prime}\right) K\left(Y_{1}-x_{1}\right)^{5}, \tag{161}
\end{align*}
$$

where $K$ is a constant since $f_{c}$ has bounded third derivative. Note that both $f_{c}^{\prime}\left(x_{1}\right)$ and $f_{c}^{\prime \prime}\left(x_{1}\right)$ are bounded as well. Therefore, taking expectation over $Y_{1}$ and using $\hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)=$ $o\left(d^{1 / 2}\right), \sup _{x^{d}} \hat{M}_{x^{d}}^{\prime \prime}=o\left(d^{1 / 2}\right)$ in Lemma C.1, we have

$$
\begin{equation*}
\mathbb{E}_{Y_{1}}\left\{\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \hat{M}_{x^{d}}\left(Y_{1}\right)\right\}=\left[\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right) \hat{M}_{x^{d}}\left(x_{1}\right)+f_{c}^{\prime}\left(x_{1}\right) \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)\right] \frac{\ell^{2}}{d-1}+o\left(d^{-1}\right) \tag{162}
\end{equation*}
$$

Finally, by Assumption (A6), we have

$$
\begin{align*}
& f_{c}^{\prime}\left(x_{1}\right) \hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right) \hat{M}_{x^{d}}\left(x_{1}\right)  \tag{163}\\
& =2 \Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right)\left(\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime}\left(x_{1}\right) \frac{\mathrm{d}\left[\log \pi_{1}(x)+\log \pi_{-1}\left(x_{-1} \mid x\right)\right]}{\mathrm{d} x}\left(x_{1}\right)\right)  \tag{164}\\
& =2 \Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right)\left(\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime}\left(x_{1}\right) \frac{\mathrm{d} \log \pi_{1 \mid-1}\left(x \mid x_{-1}\right)}{\mathrm{d} x}\left(x_{1}\right)\right)  \tag{165}\\
& \rightarrow 2 \Phi\left(-\frac{\ell I\left(x^{d}\right)^{1 / 2}}{2}\right)\left(\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime}\left(x_{1}\right) \frac{\mathrm{d} \log \tilde{\pi}(x)}{\mathrm{d} x}\left(x_{1}\right)\right)  \tag{166}\\
& \rightarrow 2 \Phi\left(-\frac{\ell \bar{I}^{1 / 2}}{2}\right)\left(\frac{1}{2} f_{c}^{\prime \prime}\left(x_{1}\right)+\frac{1}{2} f_{c}^{\prime}\left(x_{1}\right) \frac{\mathrm{d} \log \tilde{\pi}(x)}{\mathrm{d} x}\left(x_{1}\right)\right), \tag{167}
\end{align*}
$$

which implies that $\mathbb{E}_{Y_{1}}\left\{d\left[f_{c}\left(Y_{1}\right)-f_{c}\left(x_{1}\right)\right] \hat{M}_{x^{d}}\left(Y_{1}\right)\right\} \quad \rightarrow \quad\left(G f_{c}\right)\left(x_{1}\right)$ where $h(\ell)$ $:=2 \ell^{2} \Phi(-\ell \sqrt{\bar{I}} / 2)$.

## C.1. Proof of Lemma C. 1

The proof is quite tedious. In order to simplify the notations, we first introduce the following lemma.

Lemma C.2. For the function $M(y)$ defined by

$$
\begin{equation*}
M(y)=\Phi\left(f(y) g(y)-\frac{1}{2} f^{-1}(y)\right)+e^{g(y)} \Phi\left(-\frac{1}{2} f^{-1}(y)-f(y) g(y)\right) \tag{168}
\end{equation*}
$$

we have

$$
\begin{align*}
& \begin{aligned}
\frac{\mathrm{d} M(y)}{\mathrm{d} y}= & \Phi^{\prime}\left(f g-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right) \\
& +e^{g} \Phi^{\prime}\left(-f^{-1} / 2-f g\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right) \\
& +e^{g}\left(\frac{\mathrm{~d}}{\mathrm{~d} y} g\right) \Phi\left(-f g-f^{-1} / 2\right)
\end{aligned}  \tag{169}\\
& \frac{\mathrm{d}^{2} M(y)}{\mathrm{d} y^{2}}= \Phi^{\prime \prime}\left(f g-f^{-1} / 2\right)\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right]^{2}+\Phi^{\prime}\left(f g-f^{-1} / 2\right) \frac{\mathrm{d}^{2}}{\mathrm{~d} y^{2}}\left(f g-f^{-1} / 2\right)  \tag{170}\\
&+ e^{g}\left(\frac{\mathrm{~d}}{\mathrm{~d} y} g\right) \Phi^{\prime}\left(-f^{-1} / 2-f g\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)  \tag{171}\\
&+ e^{g}\left\{\Phi^{\prime \prime}\left(-f g-f^{-1} / 2\right)\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)\right]^{2}+\Phi^{\prime}\left(-f g-f^{-1} / 2\right) \frac{\mathrm{d}^{2}}{\mathrm{~d} y^{2}}\left(-f g-f^{-1} / 2\right)\right\}  \tag{172}\\
&+ e^{g}\left(\frac{\mathrm{~d}}{\mathrm{~d} y} g\right) \Phi^{\prime}\left(-f g-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)  \tag{173}\\
&+ \Phi\left(-f g-f^{-1} / 2\right)\left[e^{g}\left(\frac{\mathrm{~d}^{2}}{\mathrm{~d} y^{2}} g\right)+e^{g}\left(\frac{\mathrm{~d}}{\mathrm{~d} y} g\right)^{2}\right] \tag{174}
\end{align*}
$$

Furthermore, if $g\left(x_{1}\right)=0$, then we have

$$
\begin{align*}
\frac{\mathrm{d} M(y)}{\mathrm{d} y}\left(x_{1}\right)= & \left(\Phi^{\prime}\left(-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right.  \tag{177}\\
& +\Phi^{\prime}\left(-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)  \tag{178}\\
& \left.+\left(\frac{\mathrm{d}}{\mathrm{~d} y} g\right) \Phi\left(-f^{-1} / 2\right)\right)\left(x_{1}\right)  \tag{179}\\
= & \left(\Phi^{\prime}\left(-f^{-1} / 2\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f^{-1}\right)+\left(\frac{\mathrm{d}}{\mathrm{~d} y} g\right) \Phi\left(-f^{-1} / 2\right)\right)\left(x_{1}\right)  \tag{180}\\
= & -\Phi^{\prime}\left(-\frac{f^{-1}\left(x_{1}\right)}{2}\right) \frac{\mathrm{d} f^{-1}(y)}{\mathrm{d} y}\left(x_{1}\right)+\frac{\mathrm{d} g(y)}{\mathrm{d} y}\left(x_{1}\right) \Phi\left(-\frac{f^{-1}\left(x_{1}\right)}{2}\right) \tag{181}
\end{align*}
$$

Remark C.3. Let $g(y)=\log \frac{\pi^{d}\left(y, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)}$ and $f^{-1}(y)=\ell R_{d}^{1 / 2}(y)$ then $\hat{M}_{x^{d}}(y)=M(y)$. $\triangleleft$
Now substituting $g(y)=\log \frac{\pi^{d}\left(y, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)}$ and $f^{-1}(y)=\ell R_{d}^{1 / 2}(y)$ to Lemma C.2, we have

$$
\begin{equation*}
\hat{M}_{x^{d}}\left(x_{1}\right)=2 \Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right), \tag{182}
\end{equation*}
$$

and

$$
\begin{equation*}
\hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)=\frac{\mathrm{d} \hat{M}_{x^{d}}(y)}{\mathrm{d} y}\left(x_{1}\right) \tag{183}
\end{equation*}
$$

$$
\begin{align*}
= & \Phi\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right) \frac{\mathrm{d}\left[\log \pi_{1}(x)+\log \pi_{-1}\left(x_{-1} \mid x\right)\right]}{\mathrm{d} x}\left(x_{1}\right)  \tag{184}\\
& -\Phi^{\prime}\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right) \frac{\ell}{2 R_{d}^{1 / 2}\left(x_{1}\right)} R_{d}^{\prime}\left(x_{1}\right) . \tag{185}
\end{align*}
$$

Since $\Phi^{\prime}$ is bounded and by Eq. (136), $R_{d}^{\prime}\left(x_{1}\right) / R_{d}^{1 / 2}\left(x_{1}\right) \rightarrow 0$, therefore

$$
\begin{equation*}
\Phi^{\prime}\left(-\frac{\ell R_{d}^{1 / 2}\left(x_{1}\right)}{2}\right) \frac{\ell}{2 R_{d}^{1 / 2}\left(x_{1}\right)} R_{d}^{\prime}\left(x_{1}\right)=o(1) . \tag{186}
\end{equation*}
$$

Also, $\hat{M}_{x^{d}}^{\prime}\left(x_{1}\right)=o\left(d^{1 / 2}\right)$ since $\frac{\partial \log \pi^{d}}{\partial x_{i}}=\mathcal{O}\left(d^{\alpha / 2}\right)=o\left(d^{1 / 2}\right)$.
Now we prove $\sup _{x^{d}} \hat{M}_{x^{d}}^{\prime \prime}=o\left(d^{1 / 2}\right)$. For simplicity, we keep the notations of $f$ and $g$ (recall that $g(y)=\log \frac{\pi^{d}\left(y, x_{-1}\right)}{\pi^{d}\left(x^{d}\right)}$ and $\left.f^{-1}(y)=\ell R_{d}^{1 / 2}(y)\right)$ and use the results in Appendix B.5. Since $\Phi, \Phi^{\prime}, \Phi^{\prime \prime}$ are bounded, it suffices to bound all the following terms to be $o\left(d^{1 / 2}\right)$ :

$$
\begin{align*}
& {\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right]^{2}, \quad \frac{\mathrm{~d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right), \quad \exp (g)\left(\frac{\mathrm{d} g}{\mathrm{~d} y}\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right),}  \tag{187}\\
& \exp (g)\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right]^{2}, \quad \exp (g) \frac{\mathrm{d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right), \quad \exp (g)\left(\frac{\mathrm{d}^{2} g}{\mathrm{~d} y^{2}}\right), \quad \exp (g)\left(\frac{\mathrm{d} g}{\mathrm{~d} y}\right)^{2} \tag{188}
\end{align*}
$$

Next, we show that most of them can be verified using Assumption (A4+), and the results in Appendix B.5:

$$
\begin{align*}
& {\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right]^{2}=\mathcal{O}\left[\left(\sup _{x^{d} \in F_{d}^{+}} \log \pi^{d}\left(x^{d}\right) \mathcal{O}\left(d^{\alpha / 4}\right)+\sup _{x^{d} \in F_{d}^{+}} \frac{\partial \log \pi^{d}}{\partial x_{1}}\right)^{2}\right]}  \tag{1899}\\
& \quad=\mathcal{O}\left[\left(d^{\alpha / 4} \log d+d^{\alpha / 2}\right)^{2}\right]=o\left(d^{1 / 2}\right),  \tag{190}\\
& \left|e^{g}\left(\frac{\mathrm{~d} g}{\mathrm{~d} y}\right) \frac{\mathrm{d}}{\mathrm{~d} y}\left(-f g-f^{-1} / 2\right)\right|=\mathcal{O}\left[\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right) \sup _{x^{d} \in F_{d}^{+}} \frac{\partial \log \pi^{d}}{\partial x_{1}}\left(d^{\alpha / 4} \log d+d^{\alpha / 2}\right)\right]  \tag{191}\\
& \quad=o\left(d^{1 / 2-\alpha} d^{\alpha / 2}\left(d^{\alpha / 4} \log d+d^{\alpha / 2}\right)\right)=o\left(d^{1 / 2}\right),  \tag{192}\\
& \left|\exp (g)\left[\frac{\mathrm{d}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)\right]^{2}\right|=o\left(d^{1 / 2-\alpha} d^{\alpha}\right)=o\left(d^{1 / 2}\right),  \tag{193}\\
& \left|\exp (g)\left(\frac{\mathrm{d}^{2} g}{\mathrm{~d} y^{2}}\right)\right|=\mathcal{O}\left[\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right) \sup _{x^{d} \in F_{d}^{+}} \frac{\partial^{2} \log \pi^{d}}{\partial x_{1}^{2}}\right]=o\left(d^{1 / 2-\alpha}\right) \mathcal{O}\left(d^{\alpha}\right)=o\left(d^{1 / 2}\right),  \tag{194}\\
& \left|\exp (g)\left(\frac{\mathrm{d} g}{\mathrm{~d} y}\right)^{2}\right|=\mathcal{O}\left[\sup _{x^{d} \in F_{d}^{+}} \pi^{d}\left(x^{d}\right) \sup _{x^{d} \in F_{d}^{+}}\left(\frac{\partial \log \pi^{d}}{\partial x_{1}^{2}}\right)^{2}\right]=o\left(d^{1 / 2-\alpha}\right) \mathcal{O}\left(d^{\alpha / 2}\right)^{2}=o\left(d^{1 / 2}\right) . \tag{195}
\end{align*}
$$

The only terms left are $\frac{\mathrm{d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)$ and $\exp (g) \frac{\mathrm{d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)$. Therefore, it suffices to show

$$
\begin{equation*}
\frac{\mathrm{d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)=\mathcal{O}\left(d^{\alpha}\right) \tag{196}
\end{equation*}
$$

Note that

$$
\begin{align*}
& \frac{\mathrm{d}^{2}}{\mathrm{~d} y}\left(f g-f^{-1} / 2\right)=\frac{\mathrm{d}}{\mathrm{~d} y}\left(f^{\prime} g+g^{\prime} f-\frac{1}{2} \mathrm{~d} f^{-1}\right)  \tag{197}\\
& =\frac{\mathrm{d}}{\mathrm{~d} y}\left[\frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}} g+\frac{1}{R_{d}^{1 / 2}} g^{\prime}-\frac{1}{2} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}\right]  \tag{198}\\
& =\frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}} g^{\prime}+\left(\frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}\right)^{\prime} g+\frac{1}{R_{d}^{1 / 2}} g^{\prime \prime}+\left(\frac{1}{R_{d}^{1 / 2}}\right)^{\prime} g^{\prime}-\frac{1}{2}\left(\frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}\right)^{\prime} \tag{199}
\end{align*}
$$

Note that we have shown $R_{d}^{\prime}=o\left(R_{d}^{1 / 2}\right)$ in Appendix B.5. Similarly, we also can show using Assumption (A3+) that

$$
\begin{align*}
R_{d}^{\prime \prime} & =\frac{1}{d-1}\left(\sum_{j \neq 1} f_{j} f_{j}^{\prime}\right)^{\prime}=\frac{1}{d-1} \sum_{j \neq 1}\left(f_{j}^{\prime}\right)^{2}+\frac{1}{d-1} \sum_{j \neq 1} f_{j} f_{j}^{\prime \prime}  \tag{200}\\
& \leq \frac{1}{d-1} \sum_{j \neq 1}\left(f_{j}^{\prime}\right)^{2}+\sqrt{\frac{1}{d-1} \sum_{j \neq 1} f_{j}^{2}} \sqrt{\frac{1}{d-1} \sum_{j \neq 1}\left(f_{j}^{\prime \prime}\right)^{2}}  \tag{201}\\
& =\mathcal{O}\left(l_{d} / d\right) o\left(\left(\sqrt{d / l_{d}}\right)^{2}\right)+o\left(R_{d}^{1 / 2} \sqrt{l_{d} / d\left(\sqrt{d / l_{d}}\right)^{2}}\right)=o\left(R_{d}^{1 / 2}\right), \tag{202}
\end{align*}
$$

where $f_{j}(x):=\frac{\partial \log \pi_{-1}\left(x_{-1} \mid x_{1}=x\right)}{\partial x_{j}}$. Therefore $R_{d}^{\prime \prime}=o\left(R_{d}^{1 / 2}\right)$ as well. Finally, we can complete the proof by verifying Eq. (196) using Assumption (A4+) as follows.

$$
\begin{align*}
& \left|\frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}} g^{\prime}\right|=\mathcal{O}\left(\frac{1}{R_{d}}\right) o(1) \mathcal{O}\left(\sup _{x^{d} \in F_{d}^{+}} \frac{\partial \log \pi^{d}}{\partial x_{1}}\right)=\mathcal{O}\left(d^{\alpha / 4}\right) o\left(d^{\alpha / 2}\right)=o\left(d^{\alpha}\right)  \tag{203}\\
& \left|\left(\frac{1}{R_{d}} \frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}\right)^{\prime} g\right|=\mathcal{O}\left[\frac{R_{d}^{\prime \prime} R_{d}^{3 / 2}+3 / 2\left(R_{d}^{\prime}\right)^{2} R_{d}^{1 / 2}}{R_{d}^{3}} g\right]=\mathcal{O}\left[\frac{1}{R_{d}^{3 / 2}}\left(R_{d}^{\prime \prime} g\right)\right]  \tag{204}\\
& =\mathcal{O}\left(d^{\alpha / 4}\right) o(1) \mathcal{O}\left(d^{\alpha / 2}\right)=o\left(d^{\alpha}\right),  \tag{205}\\
& \left|\frac{1}{R_{d}^{1 / 2}} g^{\prime \prime}\right|=\mathcal{O}\left(\sup _{x^{d} \in F_{d}^{+}} \frac{\partial^{2} \log \pi^{d}}{\partial x_{1}^{2}}\right)=o\left(d^{\alpha}\right),  \tag{206}\\
& \left|\left(\frac{1}{R_{d}^{1 / 2}}\right)^{\prime} g^{\prime}\right|=\mathcal{O}\left(\frac{1}{2} \frac{1}{R_{d}^{3 / 2} R_{d}^{\prime} g^{\prime}}\right)=o\left(1 / R_{d}\right) \mathcal{O}\left(\sup _{x^{d} \in F_{d}^{+}} \frac{\partial \log \pi^{d}}{\partial x_{1}}\right)=\mathcal{O}\left(d^{\alpha / 4}\right) o\left(d^{\alpha / 2}\right)=o\left(d^{\alpha}\right),  \tag{207}\\
& \left|\left(\frac{R_{d}^{\prime}}{R_{d}^{1 / 2}}\right)^{\prime}\right|=\left|\frac{R_{d}^{\prime \prime} R_{d}^{1 / 2}-\frac{1}{2}\left(R_{d}^{\prime}\right)^{2} \frac{1}{R_{d}^{1 / 2}}}{R_{d}}\right|=\mathcal{O}\left(R_{d}^{\prime \prime} / R_{d}^{1 / 2}\right)=o(1)=o\left(d^{\alpha}\right) . \tag{208}
\end{align*}
$$

## Appendix D. Proof of Theorem 3.21

We follow the same approach as in the proof of Roberts and Rosenthal [58, Proposition 3]. The idea is to follow the proof of Theorem 3.19 except in the proof of Eq. (79), we need a stronger version of Lemma A. 3 to determine the sequence of "typical sets" $\left\{F_{d}^{\prime}\right\}$.

Given fixed time $t$, considering the sequence of "typical sets" $\left\{F_{d}^{\prime}\right\}$ defined by

$$
\begin{equation*}
F_{d}^{\prime}:=\left\{x^{d}:\left|R_{d}+S_{d}\right| \leq d^{-\delta}\right\}, \tag{209}
\end{equation*}
$$

where $\delta>0$ and we used $R_{d}$ and $S_{d}$ to denote $R_{d}^{(1)}$ and $S_{d}^{(1)}$ for simplicity. We need to guarantee that when $d$ is large enough, we always have $X^{d}(\lfloor d s\rfloor) \in F_{d} \cap F_{d}^{\prime}, \forall 0 \leq s \leq t$ and this happens for almost all starting state $X_{1}^{d}(0)=x$. That is, defining

$$
\begin{equation*}
p(d, x):=\mathbb{P}\left(X(\lfloor d s\rfloor) \notin F_{d} \cap F_{d}^{\prime}, \exists 0 \leq s \leq t \mid X_{1}^{d}(0)=x\right), \tag{210}
\end{equation*}
$$

letting $\pi_{1}$ denote the marginal stationary distribution for the first coordinate, we want to show that for any given $\epsilon>0$, as $d \rightarrow \infty$

$$
\begin{equation*}
\mathbb{P}_{x \sim \pi_{1}}[p(d, x) \geq \epsilon, \text { infinite often }]=0 . \tag{211}
\end{equation*}
$$

We prove it using Borel-Cantelli Lemma. Note that the application of Borel-Cantelli lemma is valid since we have assumed all of the processes are jointly defined on the same probability space as independent processes. First, note that

$$
\begin{equation*}
\mathbb{E}_{x \sim \pi_{1}}[p(d, x)]=d t \mathbb{P}_{\pi^{d}}\left(\left(F_{d} \cap F_{d}^{\prime}\right)^{c}\right)=d t \mathbb{P}_{\pi^{d}}\left(F_{d}^{c} \cup\left(F_{d}^{\prime}\right)^{c}\right) \leq d t \mathbb{P}_{\pi^{d}}\left(F_{d}^{c}\right)+d t \mathbb{P}_{\pi^{d}}\left(\left(F_{d}^{\prime}\right)^{c}\right) \tag{212}
\end{equation*}
$$

For any given $\epsilon>0$, we have

$$
\begin{align*}
& \sum_{d=2}^{\infty} \mathbb{P}(p(x, d) \geq \epsilon) \leq \sum_{d=2}^{\infty} \frac{\mathbb{E}_{x \sim \pi_{1}}[p(d, x)]}{\epsilon}  \tag{213}\\
& \leq \frac{d t}{\epsilon} \sum_{d=2}^{\infty} \mathbb{P}_{\pi^{d}}\left(\left|R_{d}+S_{d}\right|>d^{-\delta}\right)+\frac{d t}{\epsilon} \sum_{d=2}^{\infty} \mathbb{P}\left(X^{d} \notin F_{d}\right) . \tag{214}
\end{align*}
$$

By $\pi^{d}\left(F_{d}^{c}\right)=\mathcal{O}\left(d^{-2-\delta}\right)$, we have $d t \sum_{d=2}^{\infty} \mathbb{P}\left(X^{d} \notin F_{d}\right)<\infty$. Now in order to use Borel-Cantelli Lemma, the condition we need is that for some number of moments $m$ such that

$$
\begin{equation*}
\mathbb{P}_{\pi^{d}}\left(\left|R_{d}+S_{d}\right|>d^{-\delta}\right) \leq \frac{\mathbb{E}\left|R_{d}+S_{d}\right|^{m}}{d^{-m \delta}}=d^{m \delta} \mathbb{E}\left|R_{d}+S_{d}\right|^{m}=\mathcal{O}\left(d^{-2-\delta}\right), \tag{215}
\end{equation*}
$$

which leads to $\sum_{d=2}^{\infty} \mathbb{P}(p(x, d) \geq \epsilon)<\infty$. In order to obtain non-trivial conditions, we let $m=5$ and Assumption (A2++) implies $\mathbb{E}\left|R_{d}+S_{d}\right|^{5}=\mathcal{O}\left(d^{-2-6 \delta}\right)$. We can then use this sequence of typical sets $\left\{F_{d}^{\prime}\right\}$ in the proof of Theorem 3.19 to replace the sequence of $\left\{F_{d}^{\prime}\right\}$ used in Lemma A.3. The residual proof follows the same as Theorem 3.19.

## Appendix E. Proof of Proposition 4.6

Note that we have the number of parameters $d=n^{2}+n+2$ in this example. The target distribution (i.e. the posterior distribution) satisfies

$$
\begin{align*}
\pi^{d}\left(x^{d}\right) & =\mathbb{P}\left(x^{d} \mid\left\{Y_{i j}\right\}_{i, j=1}^{n}\right) \\
& \propto \frac{b^{a}}{\Gamma(a)} A^{-a-1} e^{-b / A} \prod_{j=1}^{n} \frac{1}{\sqrt{2 \pi A}} e^{-\frac{\left(\mu_{j}-v\right)^{2}}{2 A}} \prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi V}} e^{-\frac{\left(\theta_{i j}-\mu_{j}\right)^{2}}{2 V}} \frac{1}{\sqrt{2 \pi W}} e^{-\frac{\left(Y_{i j}-\theta_{i j}\right)^{2}}{2 W}} . \tag{216}
\end{align*}
$$

Clearly, this model can be represented by the graphical model in Eq. (41). It can be easily checked that the maximum number of cliques any coordinate belongs to is $n+1$ and the cardinality of cliques is bounded by constant 2, so $\sup _{k}\left|C_{k}\right|=o\left(d / m_{d}\right)=o(n)$. Furthermore, the target distribution clearly satisfies "flat tail" condition required by Proposition 4.3 since all the conditional distributions are standard distributions. Therefore, the first equation in (A1), the first equation in (A3), and (A2) hold by Proposition 4.3.

Next, we verify (A5) using Proposition 4.4. Note that this model can be represented by the graphical model in Eq. (42) using $K=3$ layers. In order to check the conditions in Proposition 4.4, note that

$$
\begin{equation*}
\log \pi^{d} \propto\left(-a-1-\frac{n}{2}\right) \log A-\frac{b}{A}-\frac{\sum_{j}\left(\mu_{j}-v\right)^{2}}{2 A}-\frac{\sum_{i, j}\left(\theta_{i j}-\mu_{j}\right)^{2}}{2 V}-\frac{\sum_{i, j}\left(Y_{i j}-\theta_{i j}\right)^{2}}{2 W} . \tag{217}
\end{equation*}
$$

Observing that, under $X^{d}=\left(v, A,\left\{\mu_{j}\right\}_{j=1}^{n},\left\{\theta_{i j}\right\}_{i, j=1}^{n}\right) \sim \pi^{d}$, we have

$$
\begin{align*}
\theta_{i j} \mid Y_{i j}, \mu_{j} & \sim \text { indep. } \mathcal{N}\left(\frac{W \mu_{j}+V Y_{i j}}{W+V}, \frac{V W}{W+V}\right), \quad i, j \in\{1, \ldots, n\},  \tag{218}\\
\mu_{j} \mid \sum_{i} \theta_{i j}, v, A & \sim \text { indep. } \mathcal{N}\left(\frac{\sum_{i} A \theta_{i j}+V v}{n A+V}, \frac{A V}{n A+V}\right), \quad i \in\{1, \ldots, n\},  \tag{219}\\
v \mid \bar{\mu}, A & \sim \mathcal{N}\left(\bar{\mu}, \frac{A}{n}\right),  \tag{220}\\
A \mid\left\{\mu_{j}\right\}, v & \sim \mathbf{I G}\left(a+\frac{n}{2}, b+\frac{1}{2} \sum_{j}\left(\mu_{j}-v\right)^{2}\right) . \tag{221}
\end{align*}
$$

Therefore, we have

$$
\begin{equation*}
\left|\frac{\partial \log \pi^{d}}{\partial A}\right|=\left|\frac{b+\frac{1}{2} \sum_{j}\left(\mu_{j}-v\right)^{2}}{A^{2}}-\frac{a+1+\frac{n}{2}}{A}\right|=\mathcal{O}_{\mathbb{P}}\left(d^{1 / 2}\right) . \tag{222}
\end{equation*}
$$

since $\frac{a+1+n / 2}{A} \rightarrow_{\mathbb{P}} \frac{a+1+n / 2}{A_{0}}=\mathcal{O}\left(d^{1 / 2}\right)$ and $\sum_{j}\left(\mu_{j}-v\right)^{2} \rightarrow_{\mathbb{P}} \sum_{j}\left(\mu_{j}-\bar{\mu}\right)^{2}+\frac{A_{0}}{n}=\mathcal{O}_{\mathbb{P}}\left(d^{1 / 2}\right)$. Other coordinates can also be verified, which are shown as follows.

$$
\begin{align*}
& \left(\frac{\partial \log \pi^{d}}{\partial v}\right)^{2}=\left(\frac{n(\bar{\mu}-v)}{A}\right)^{2}=\mathcal{O}_{\mathbb{P}}\left(\frac{n}{A}\right)=\mathcal{O}_{\mathbb{P}}(d / n),  \tag{223}\\
& \left(\frac{\partial \log \pi^{d}}{\partial \mu_{j}}\right)^{2}=\left(\frac{\sum_{i}\left(\theta_{i j}-\mu_{j}\right)}{V}-\frac{\mu_{j}-v}{A}\right)^{2}=(n A+V)^{2}\left(\frac{A \sum_{i} \theta_{i j}+V v}{n A+V}-\mu_{j}\right)^{2} \tag{224}
\end{align*}
$$

$$
\begin{align*}
& =\mathcal{O}_{\mathbb{P}}\left[(n A+V)^{2} \frac{A V}{n A+V}\right]=\mathcal{O}_{\mathbb{P}}(d / n),  \tag{225}\\
& \left(\frac{\partial \log \pi^{d}}{\partial \theta_{i j}}\right)^{2}=\left(\frac{Y_{i j}-\theta_{i j}}{V}-\frac{\theta_{i j}-\mu_{j}}{W}\right)^{2}=(W+V)^{2}\left(\frac{V Y_{i j}+W \mu_{j}}{W+V}-\theta_{i j}\right)^{2}=\mathcal{O}_{\mathbb{P}}\left(d / n^{2}\right) . \tag{226}
\end{align*}
$$

Therefore, (A5) holds by Proposition 4.4. Finally, all the other conditions in (A1), (A3), and (A4) can be verified in a similar way as in Section 4.1 for Example 4.1.
